## INTRODUCTION

For this project, we were hired by a home owner in King County, Washington who wants to renovate their home. They would like us to analyze the real estate data of the county and give them insights as to what to focus their renovation efforts on in order to increase their property's value.

Real estate prices are affected by a myriad of -what we can define as- internal parameters like the square footage, floor count, bedroom count, finishes, how many cars can fit into the garage etc. There are also parameters that we can define as external and can not (easily) be changed. These include attributes like zipcode, latitude, longitude, view from the house, and school districts. In order to accurately model and pinpoint the most important parameters that affect the sale price of a home, we need to incorporate both internal and external parameters.

We are given a dataset that includes information about the real estate in King County and will be using this dataset to create a multiple linear regression (MLR) model. We defined our goal to be to find the top 3 internal parameters that affect a home's sale price the most in King County specifically. This will ensure that the home owner can actually keep these parameters in mind while renovating rather than getting insights about external parameters that they can't necessarily do anything to change.

21417	1523300141
21418	291310100
21419	1523300157

21420 rows × 1 columns

We have 21,597 individual home sales associated with 21,420 unique homes.

## SCRUB/EXPLORE

### Addressing Null Values

```
In [10]: df.isna().sum()
```

```
Out[10]: id           0
date          0
price          0
bedrooms       0
bathrooms      0
sqft_living    0
sqft_lot        0
floors          0
```

```
waterfront      2376
view            63
condition        0
grade            0
sqft_above       0
sqft_basement    0
yr_built         0
yr_renovated     3842
zipcode          0
lat              0
long             0
sqft_living15    0
sqft_lot15       0
dtype: int64
```

To address the missing values in the view column we can take the more conservative approach and say that these 63 houses/apartments did not have a view with minimal impact to the overall dataset since we have 21597 data points overall.

```
In [11]: df['view'].fillna(0, inplace=True)
df.isna().sum()
```

```
id                0
date              0
price             0
bedrooms          0
bathrooms         0
sqft_living       0
sqft_lot          0
floors            0
waterfront        2376
view              0
condition          0

3842 rows × 21 columns

In [14]: `df['waterfront'].unique()`Out[14]: `array([nan, 0., 1.])`In [15]: `df['yr_renovated'].unique()`Out[15]: `array([ 0., 1991., nan, 2002., 2010., 1992., 2013., 1994., 1978.,
 2005., 2003., 1984., 1954., 2014., 2011., 1983., 1945., 1990.,
1988., 1977., 1981., 1995., 2000., 1999., 1998., 1970., 1989.,
2004., 1986., 2007., 1987., 2006., 1985., 2001., 1980., 1971.,
1979., 1997., 1950., 1969., 1948., 2009., 2015., 1974., 2008.,
1968., 2012., 1963., 1951., 1962., 1953., 1993., 1996., 1955.,
1982., 1956., 1940., 1976., 1946., 1975., 1964., 1973., 1957.,
1959., 1960., 1967., 1965., 1934., 1972., 1944., 1958.])`

I assumed here that the NA values meant that the place was not renovated. This is also the more conservative approach so I'm comfortable with replacing these values with 0.

In [16]: `df['yr_renovated'].fillna(0, inplace=True)`In [17]: `df.isna().sum()`Out[17]: `id 0
date 0
price 0
bedrooms 0
bathrooms 0
sqft_living 0
sqft_lot 0
floors 0
waterfront 2376
view 0
condition 0
grade 0

```

The sqft\_basement column's dtype needs to be int like other sqft columns but it is dtype object due to the "?" values.

In [21]: `df[df['sqft_basement']=='?']`

	<b>id</b>	<b>date</b>	<b>price</b>	<b>bedrooms</b>	<b>bathrooms</b>	<b>sqft_living</b>	<b>sqft_lot</b>	<b>floors</b>	<b>waterfro</b>

454 rows × 21 columns

It seems like only 454 rows out of 21,597 have ? as their value. Once again being conservative I'm going to assume that these houses/apartments don't have a basement and replace the ? with 0's and change the dtype to int.

In [22]: `df['sqft_basement'] = df['sqft_basement'].map(lambda x: x.replace('?', '0') if x=='?' else float(x))`  
`# df['sqft_basement'] = df['sqft_basement'].map(lambda x: int(float(x)))`  
`df['sqft_basement'] = df['sqft_basement'].astype('float').astype('int64')`

In [23]: `df['sqft_basement'].dtype`

Out[23]: `dtype('int64')`

In [24]: `df['renovated'] = df['yr_renovated']!=0  
df['renovated'] = df['renovated'].astype('int')  
df.head()`

Out[24]:

177 rows × 23 columns

There are duplicated entries for the same houses but since these are additional sales of the same house, they are valid data points and there is no reason to drop them.

## Linearity Check

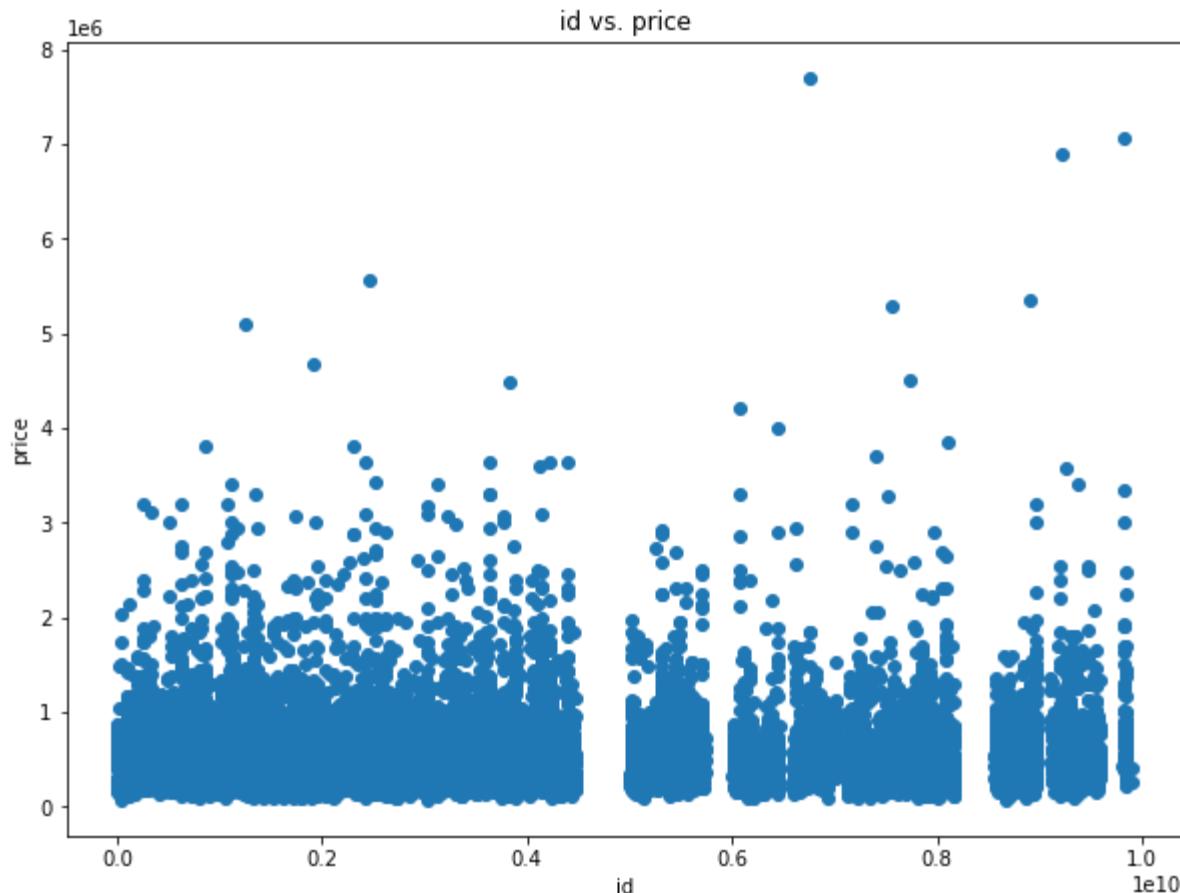

### Checking for Linearity of Parameters

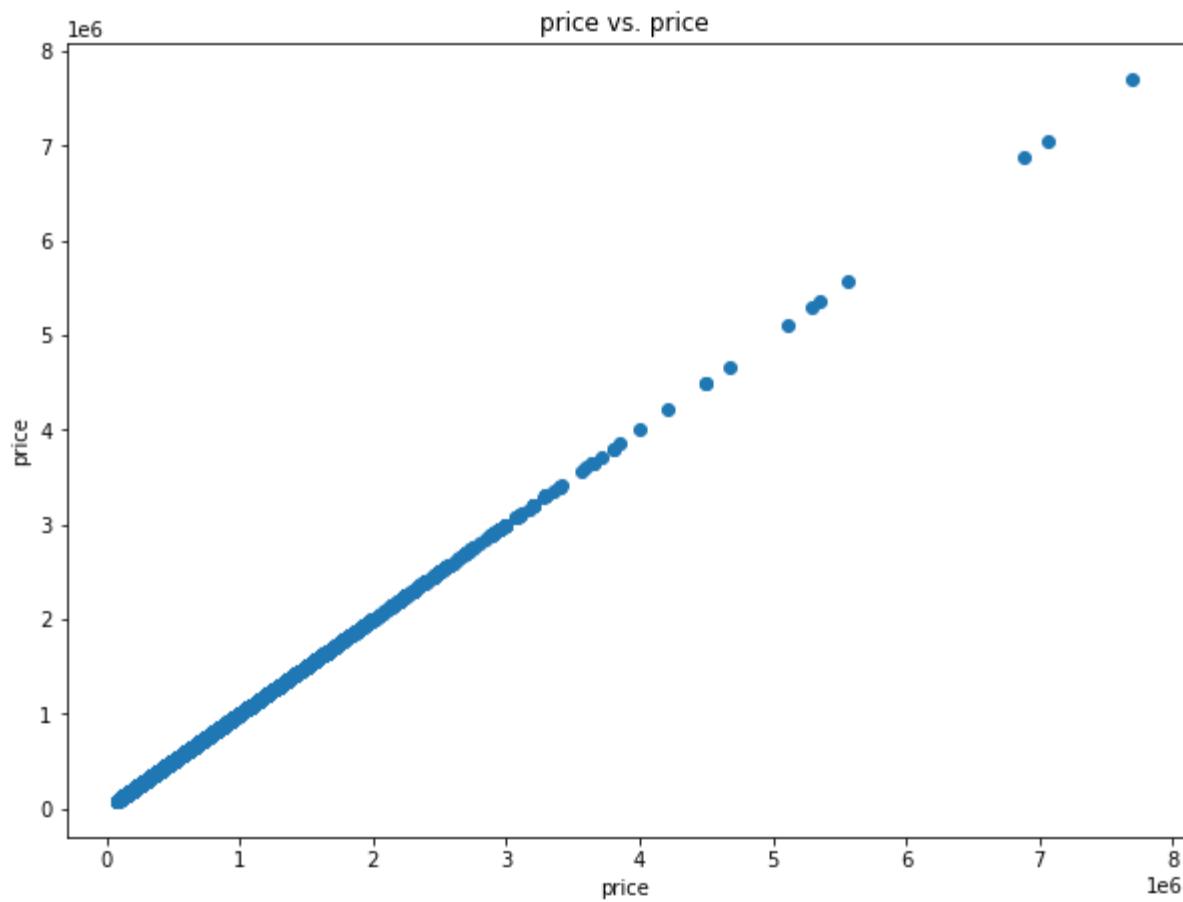

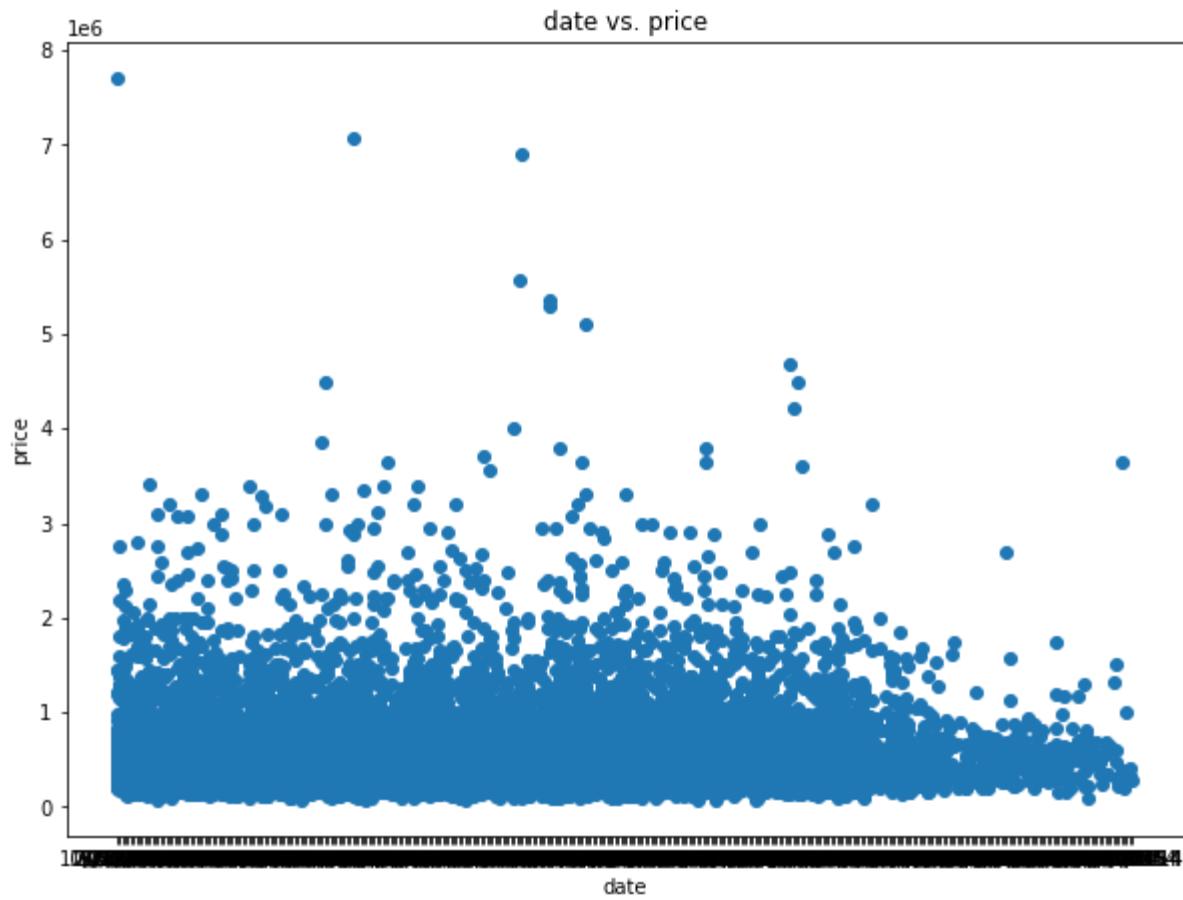

```
In [27]: import seaborn as sns

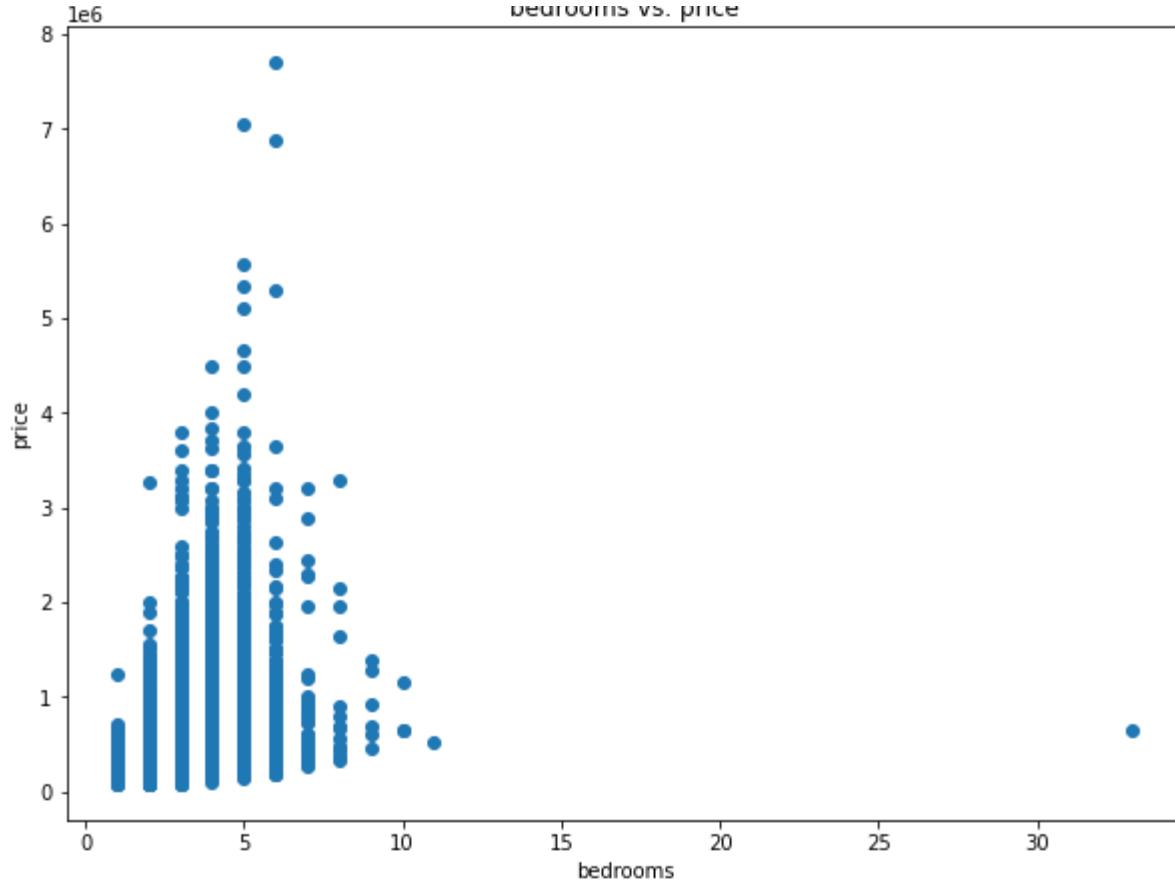

def plot(df, target='price'):
    fig, ax = plt.subplots(nrows = len(df.columns), figsize=(10,200))

    for i, col in enumerate(df.columns):
        sns.lmplot(x=col, y=target, data=df)
        ax[i].scatter(df[col], df[target])
        ax[i].set_xlabel(col)
        ax[i].set_ylabel(target)
        ax[i].set_title(f"{col} vs. {target}")
```

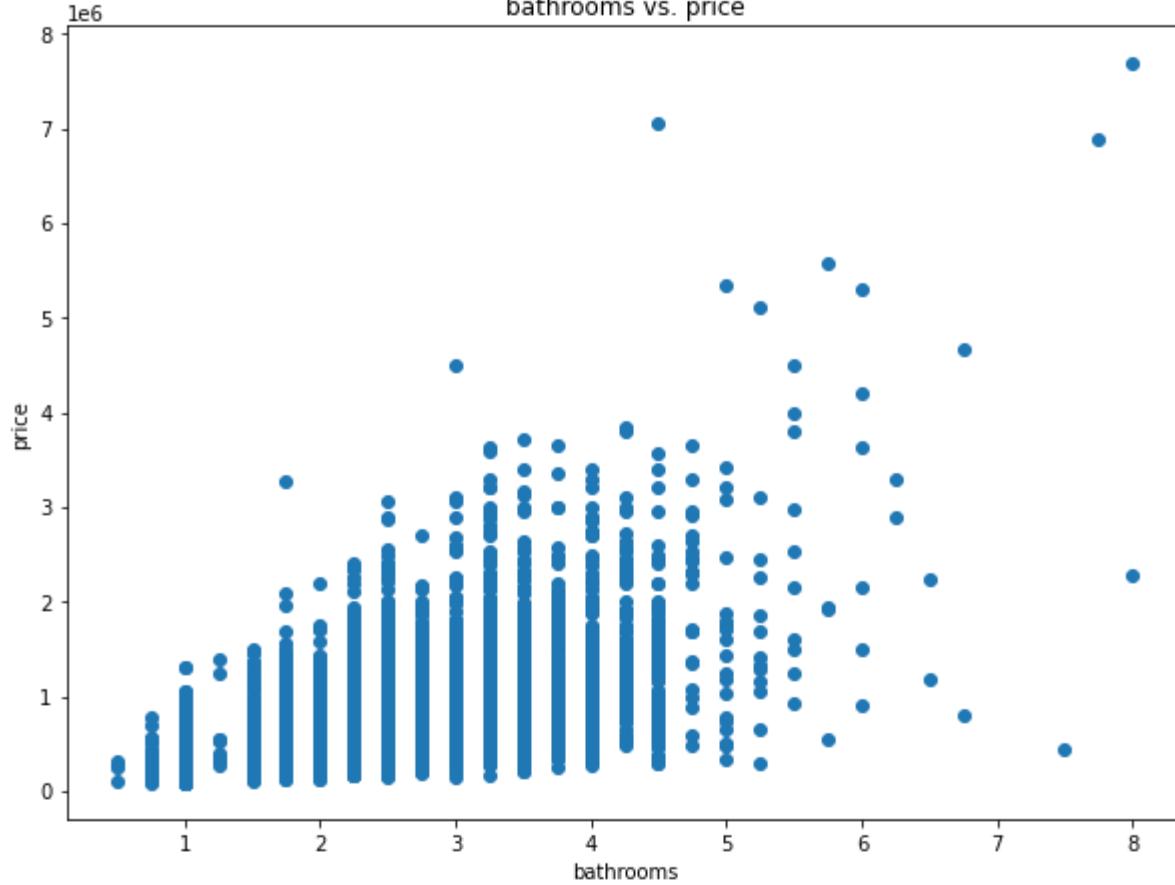

```
In [28]: plot(df=df, target='price')
```

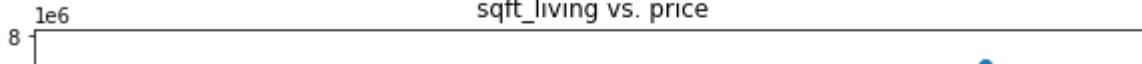

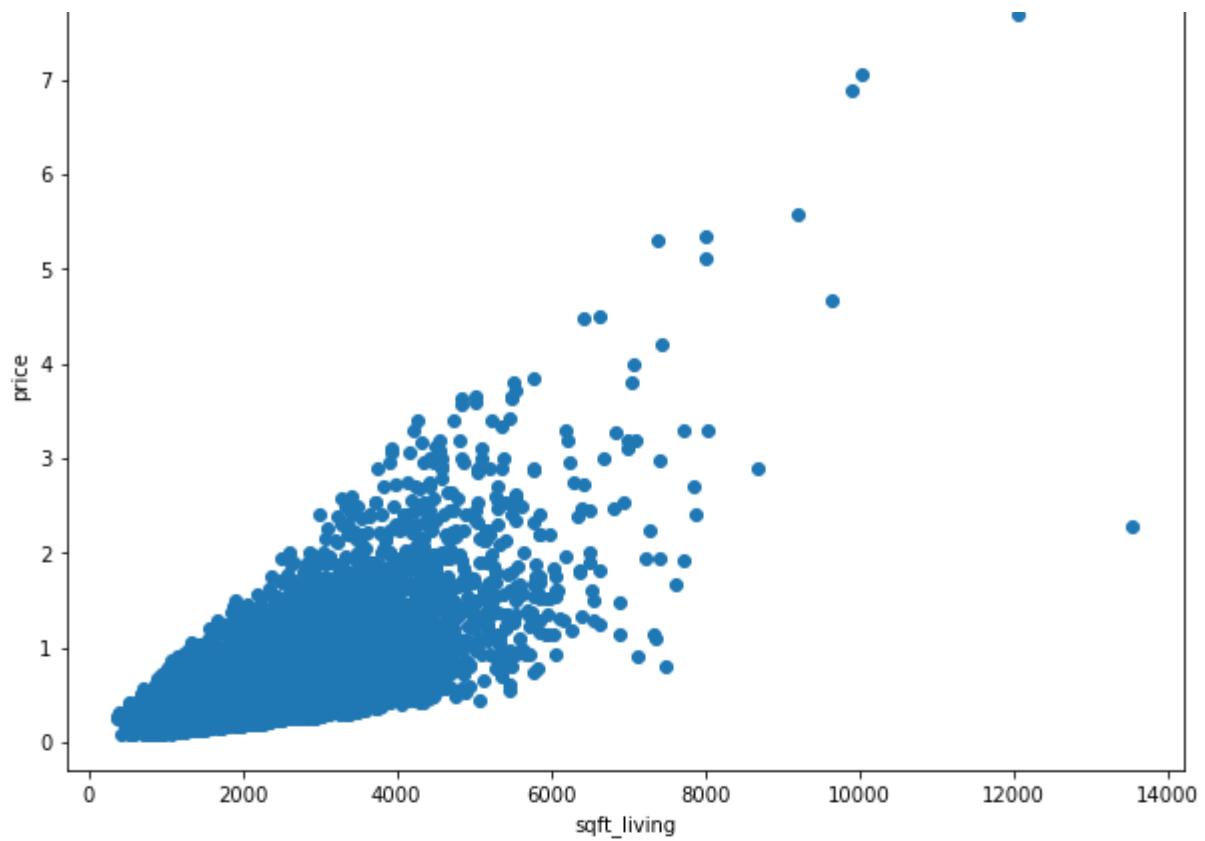

final\_notebook  
bedrooms vs. price

## bathrooms vs. price

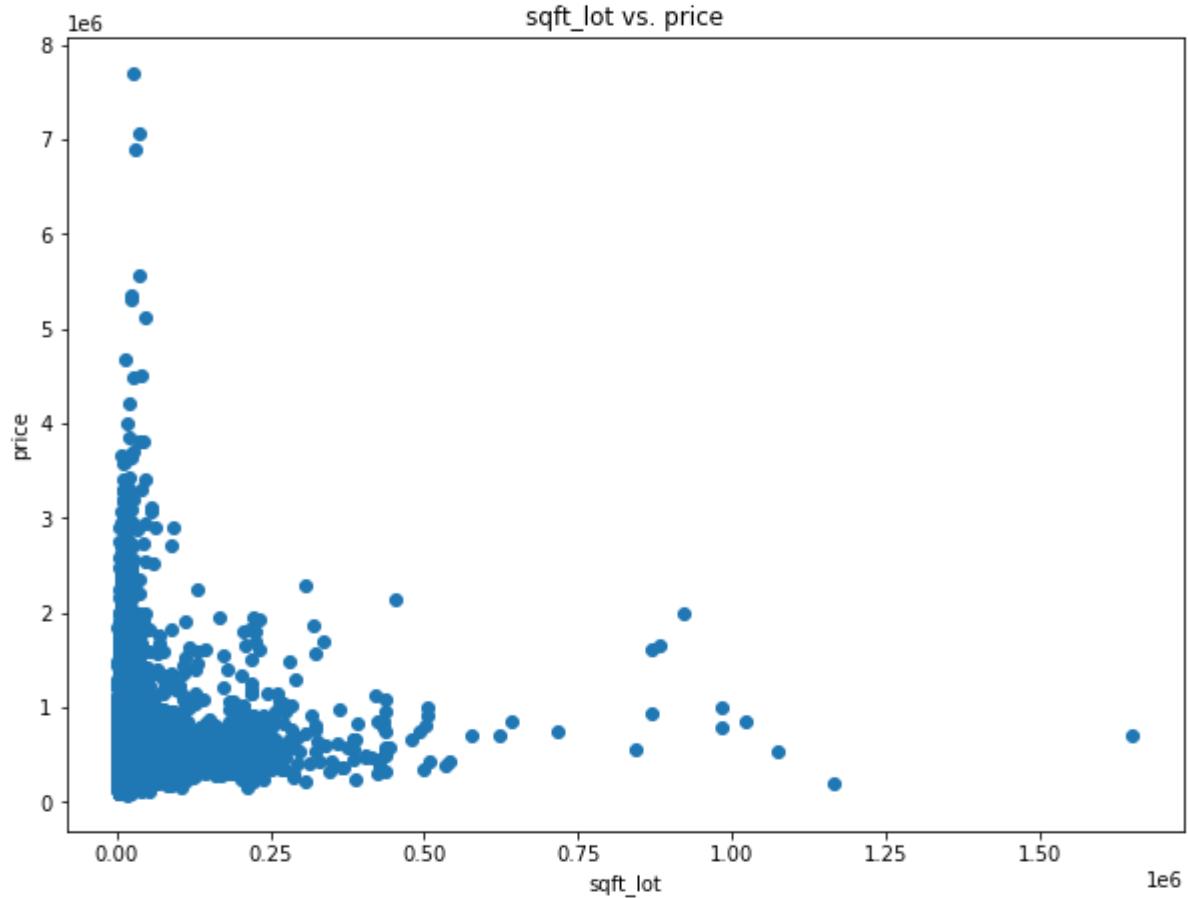

## sqft\_living vs. price

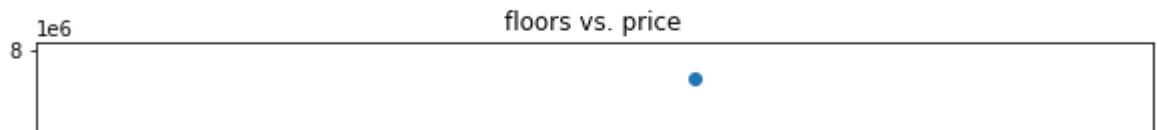

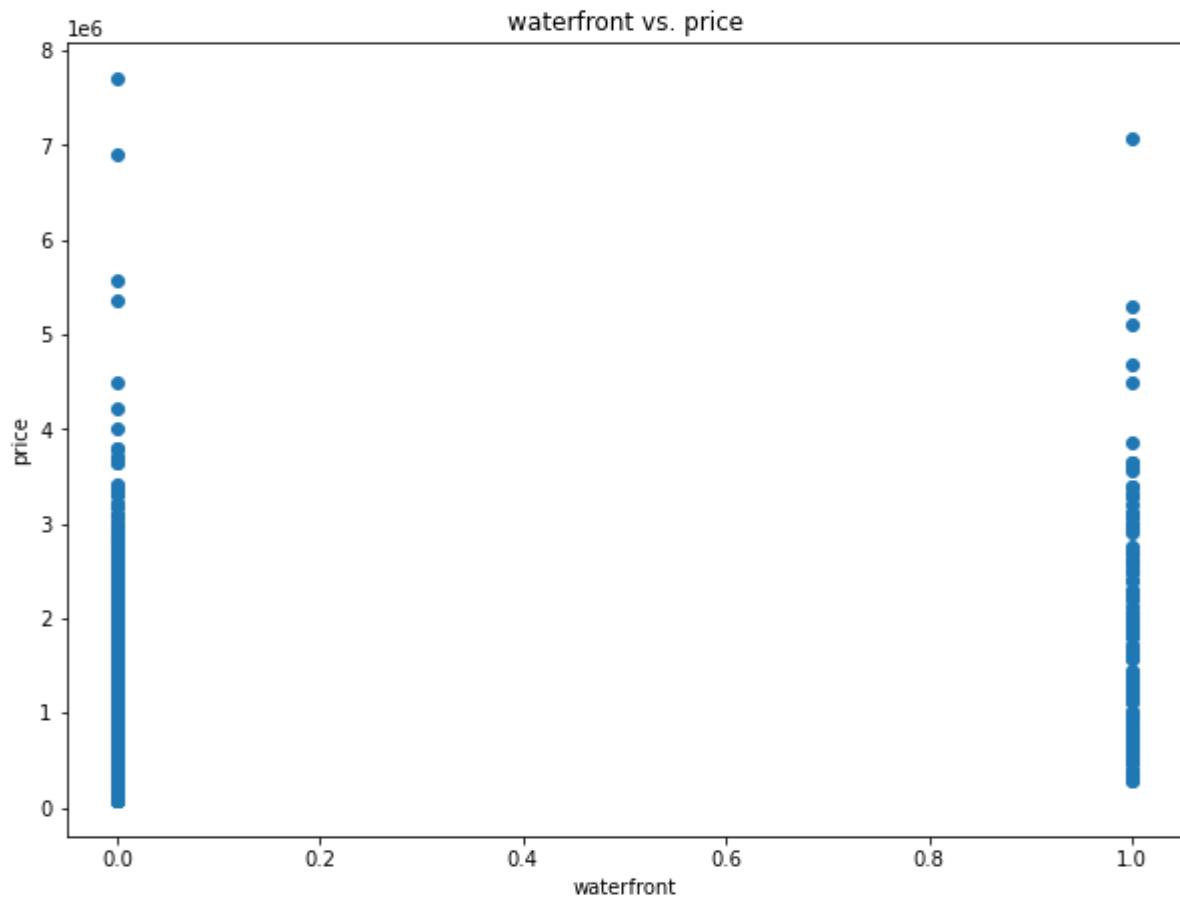

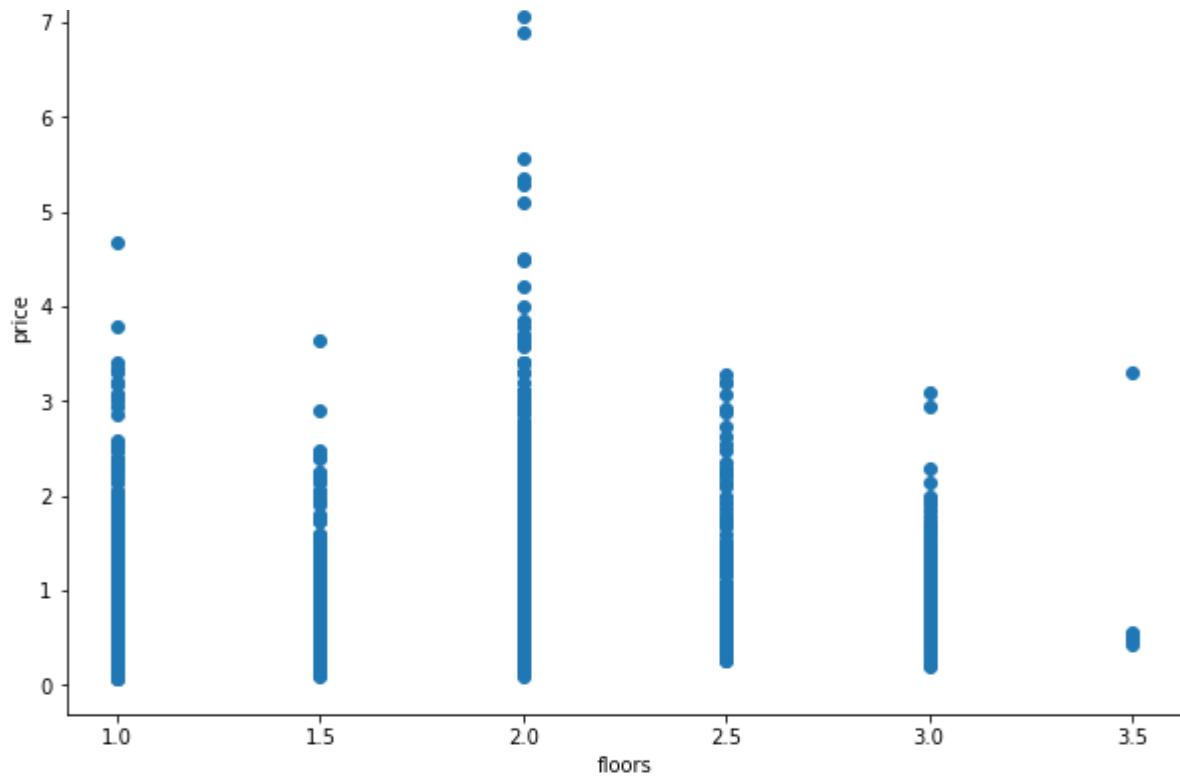

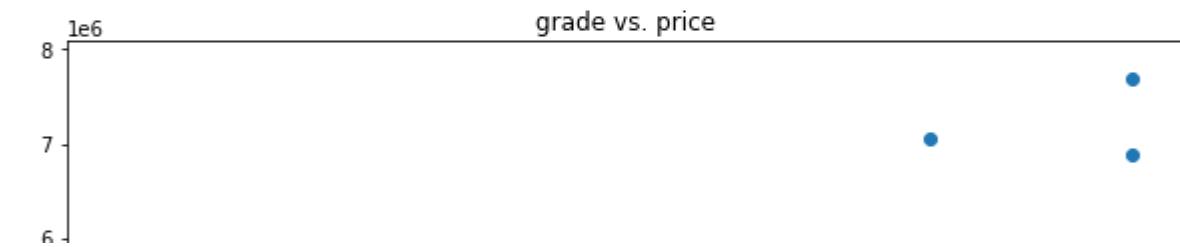

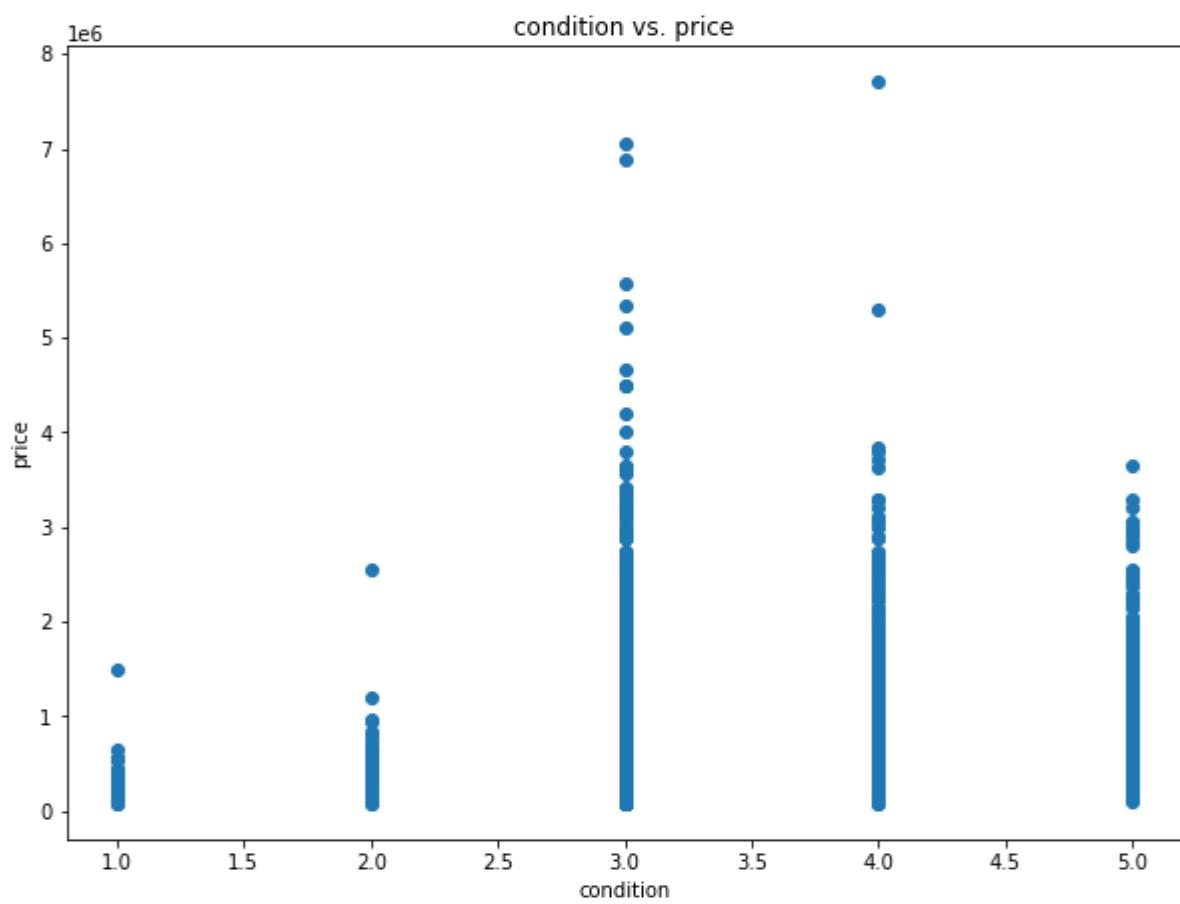

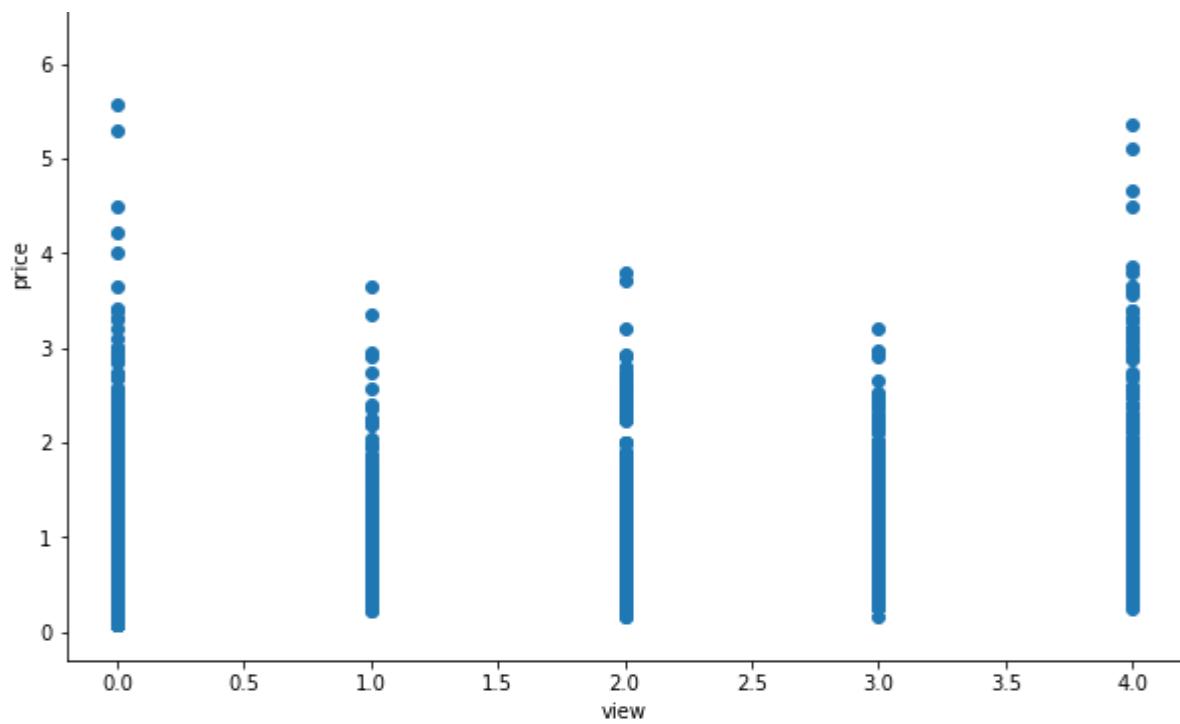

sqft\_lot vs. price

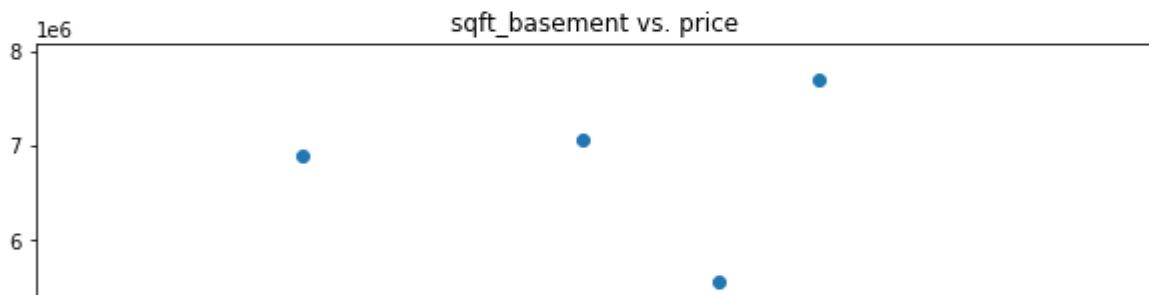

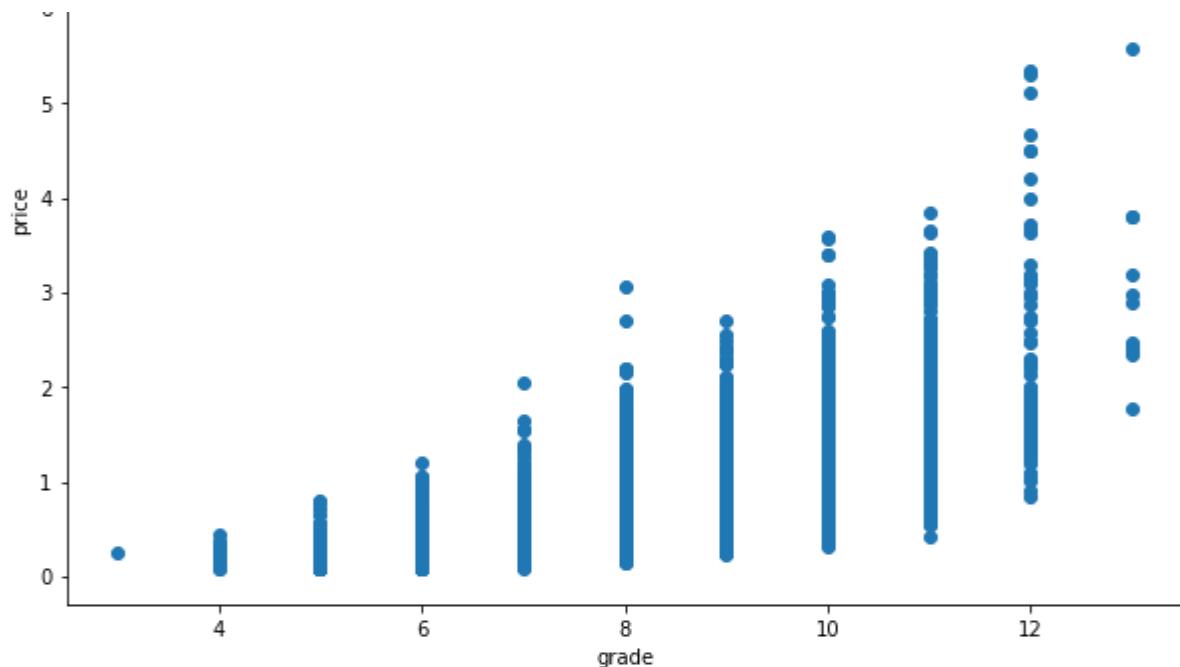

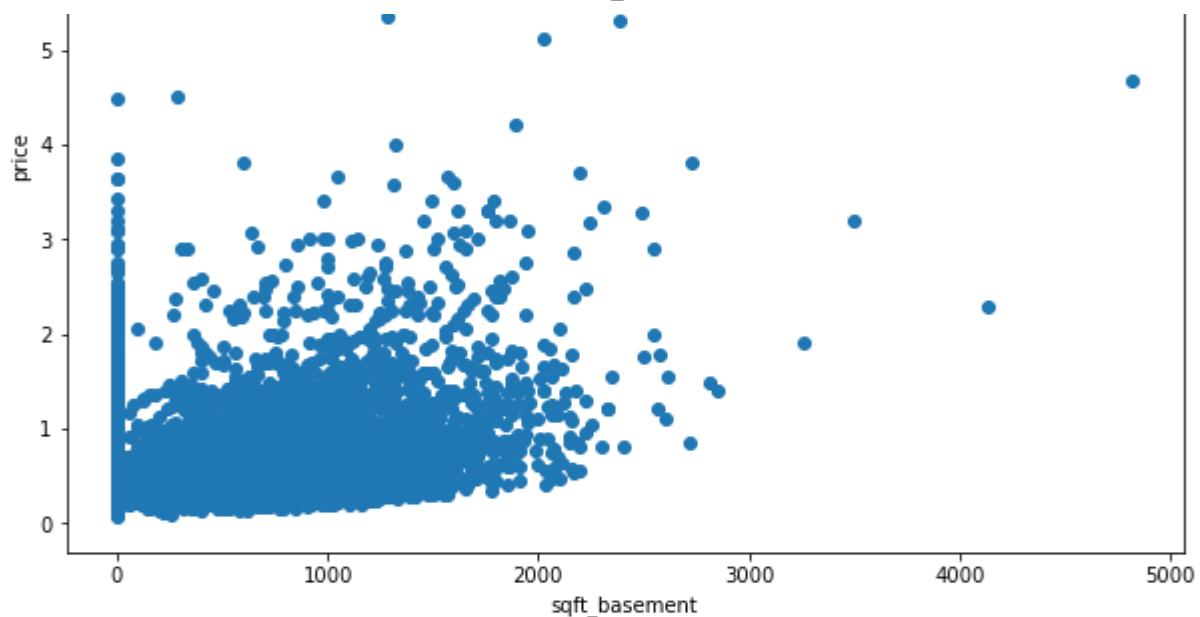

floors vs. price

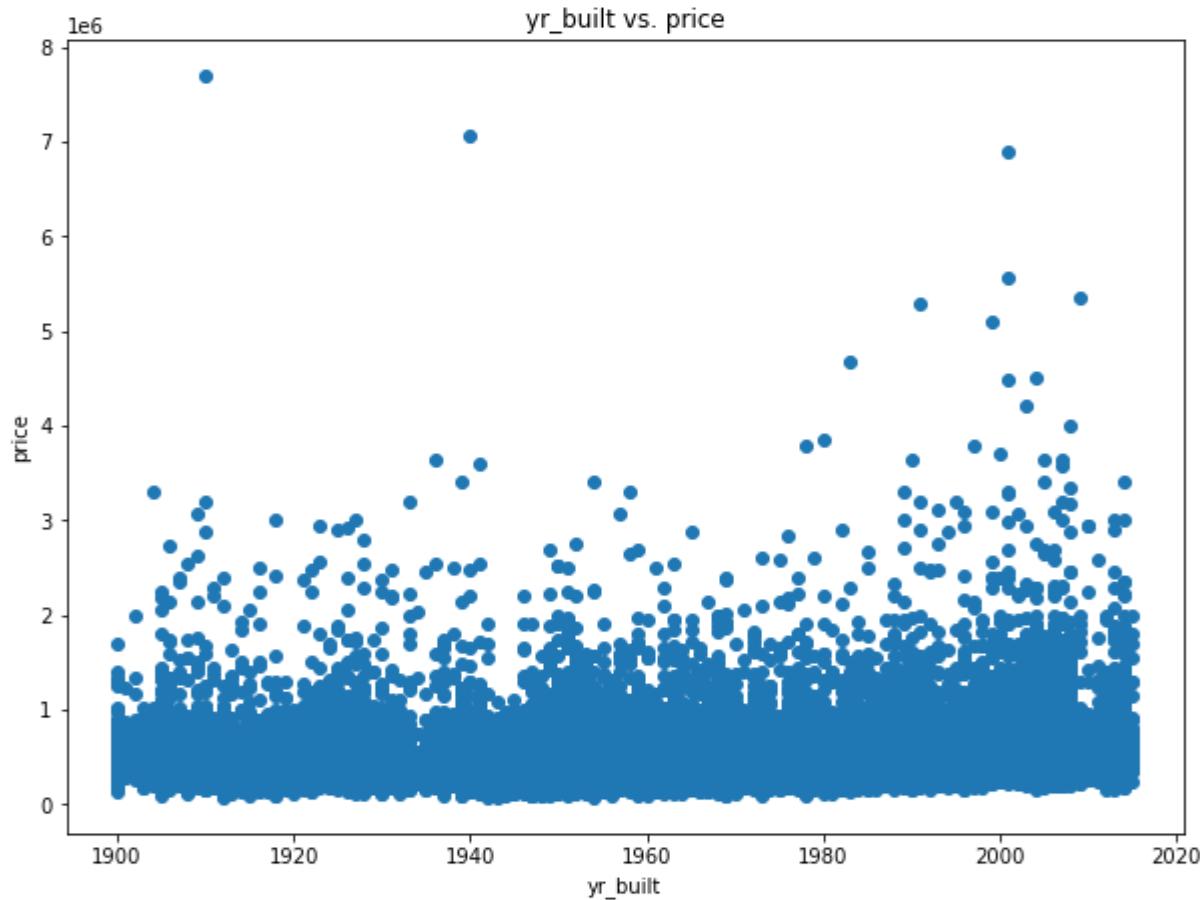

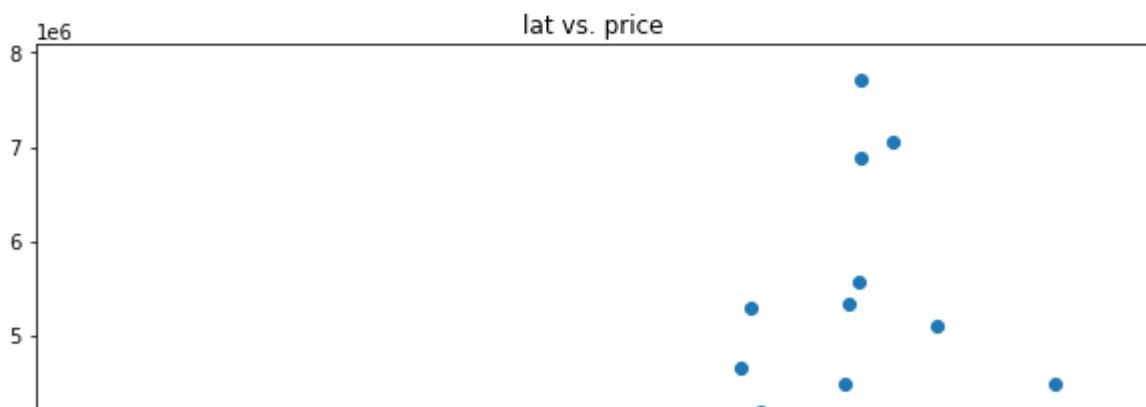

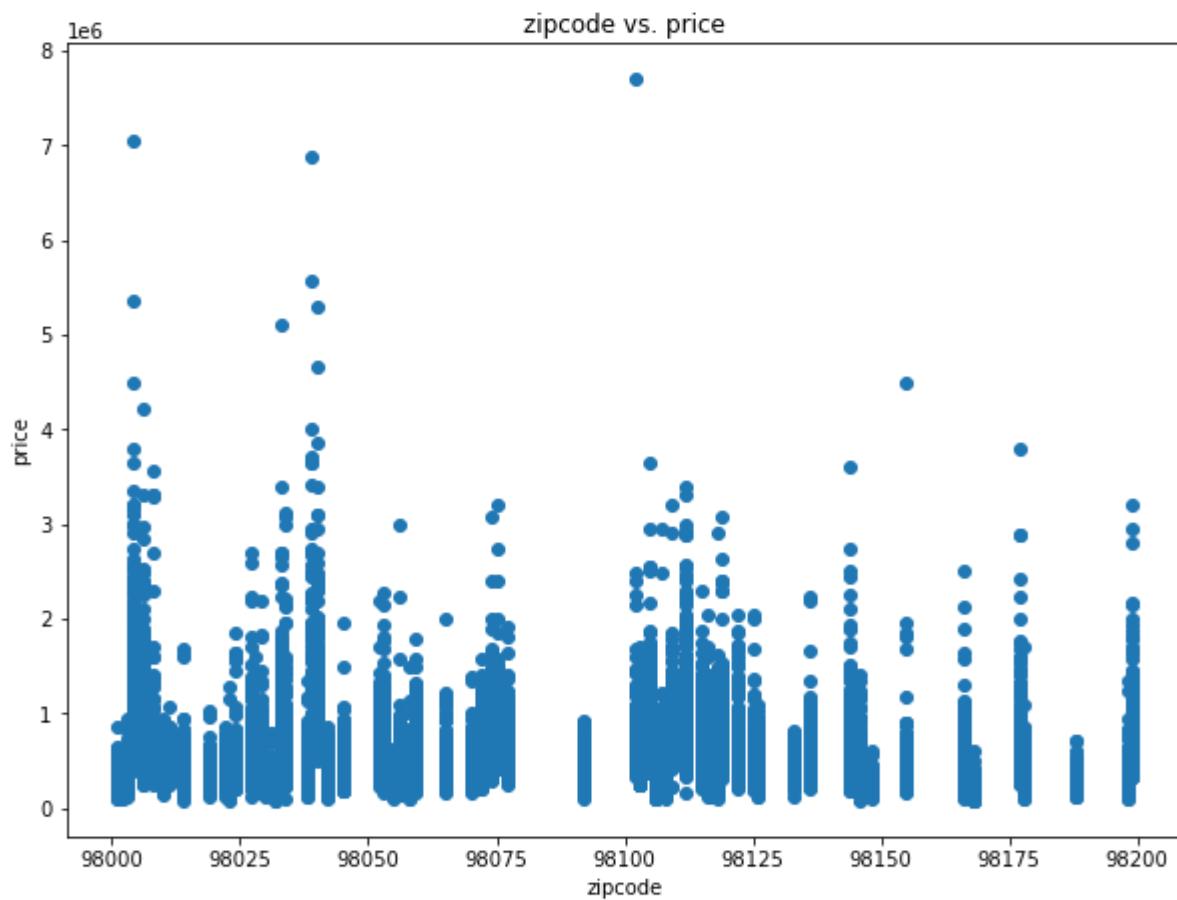

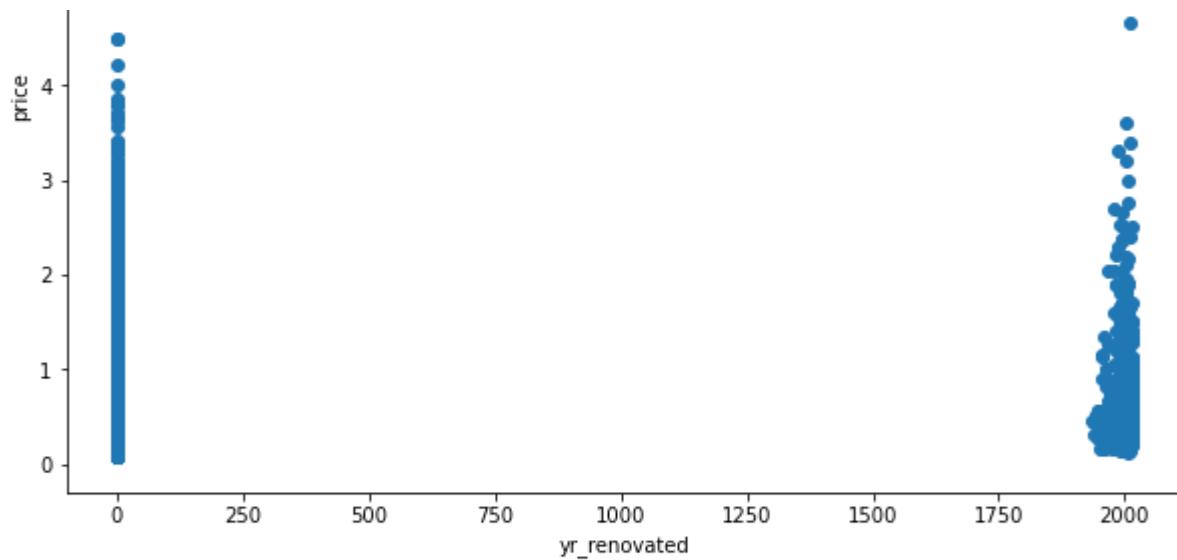

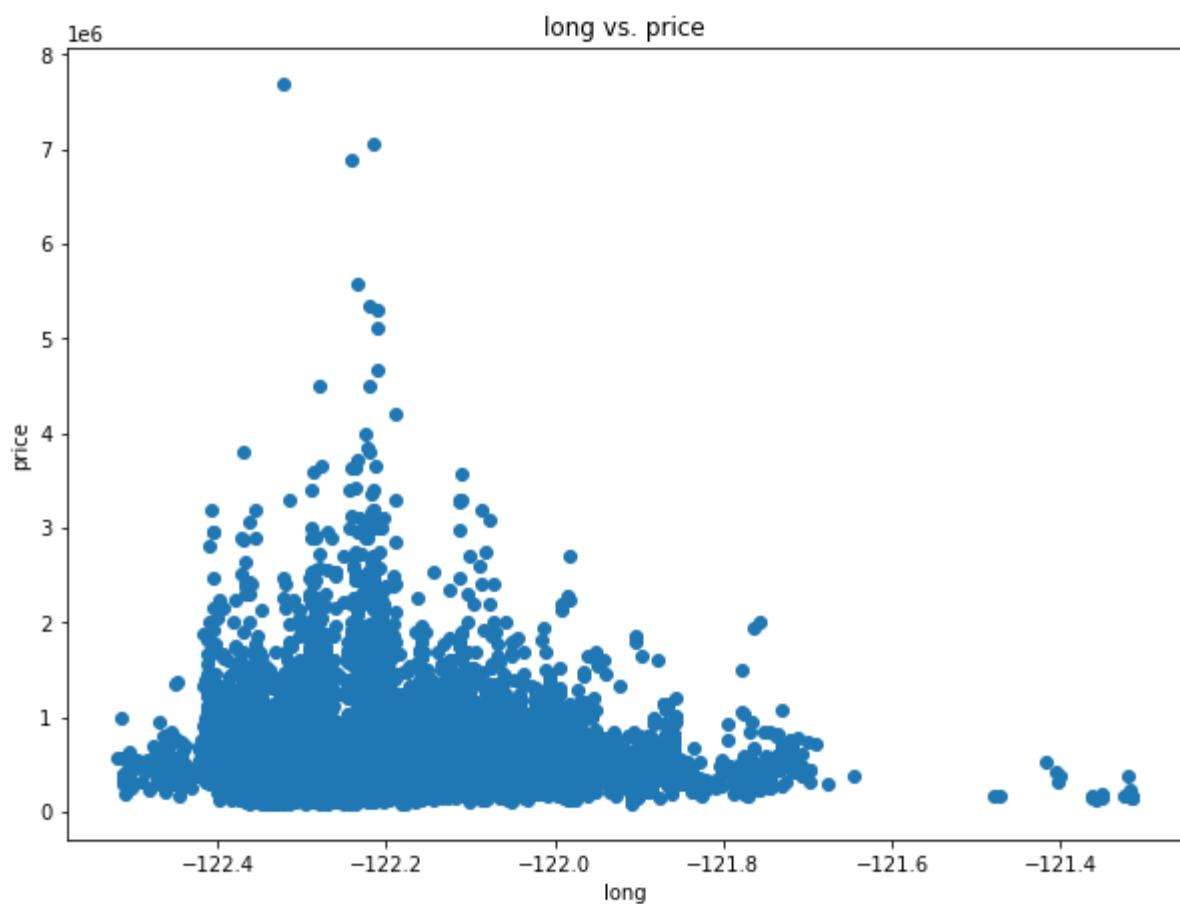

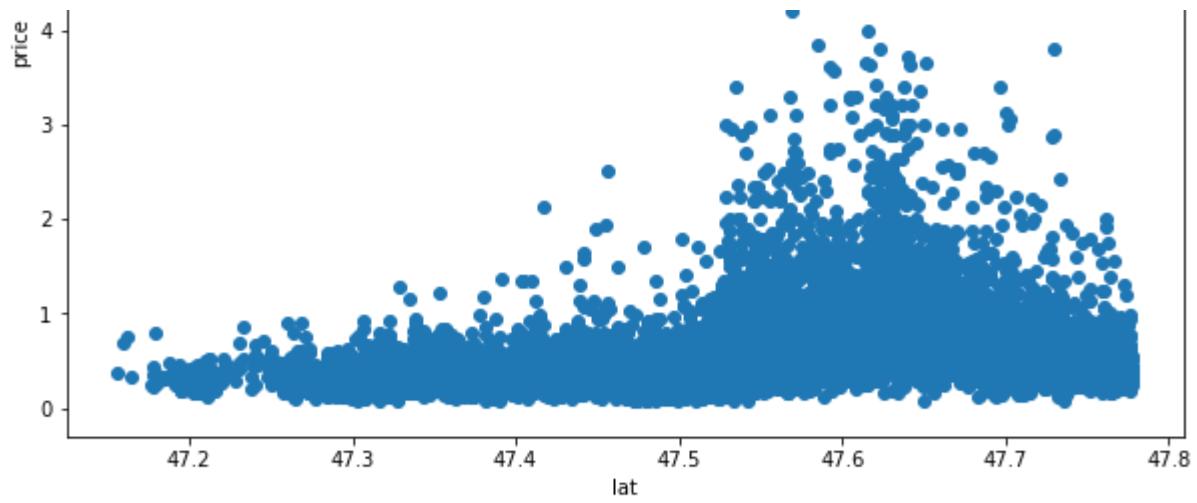

yr\_built vs. price

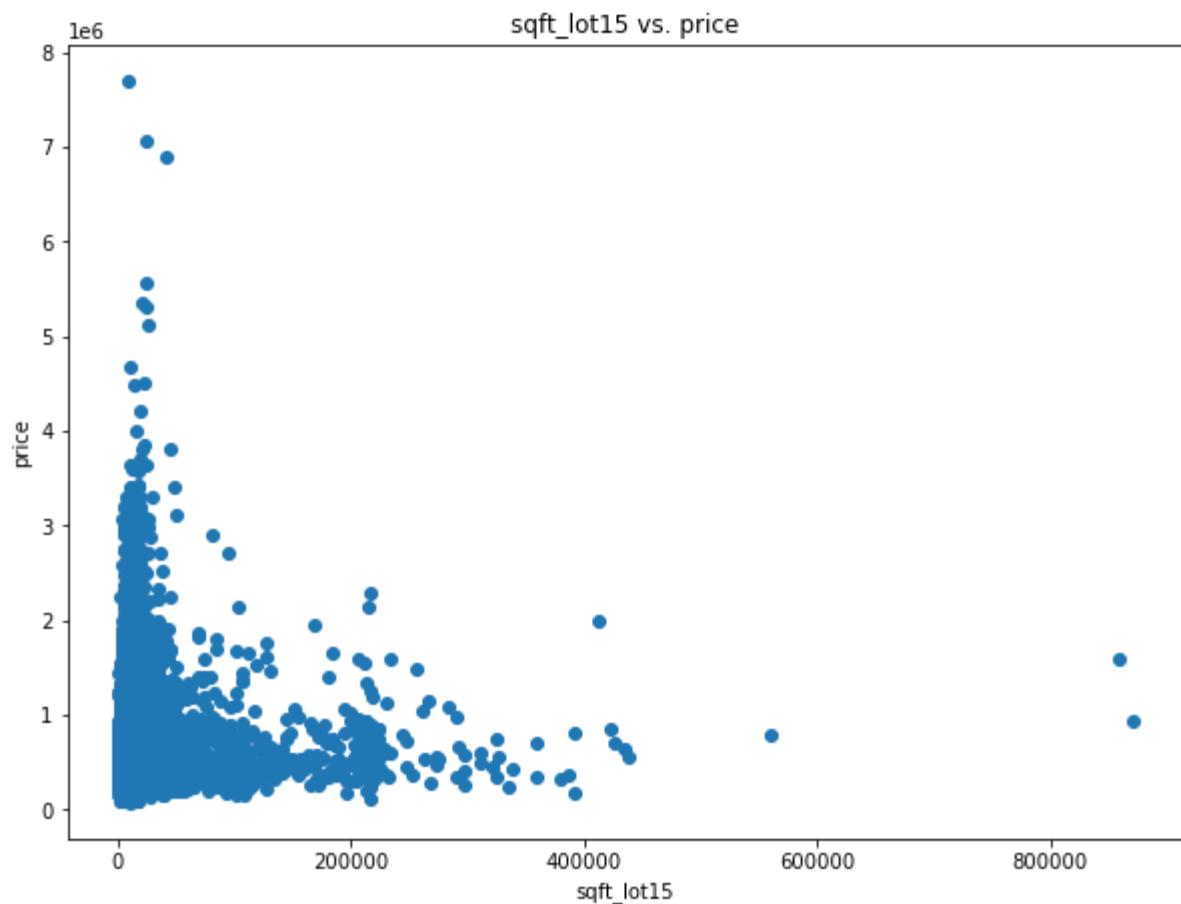

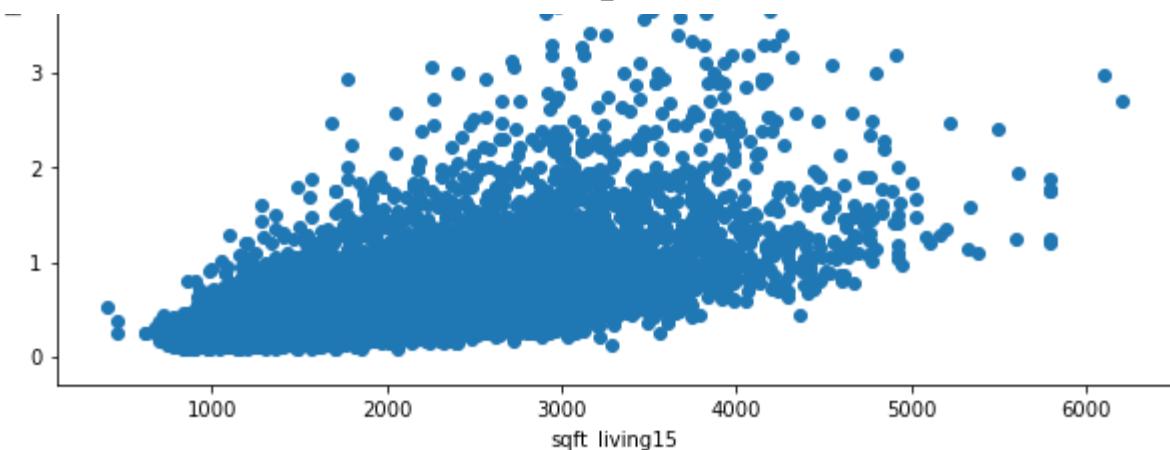

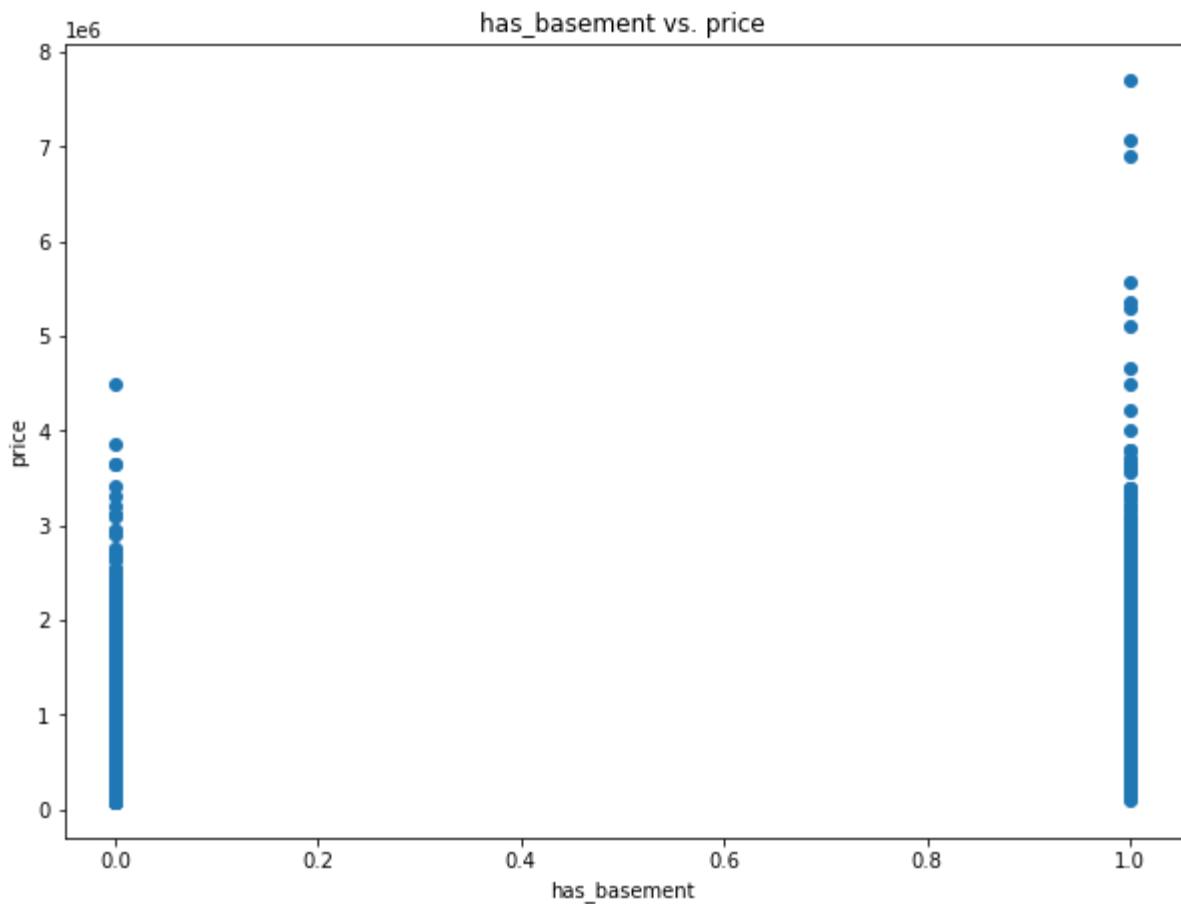

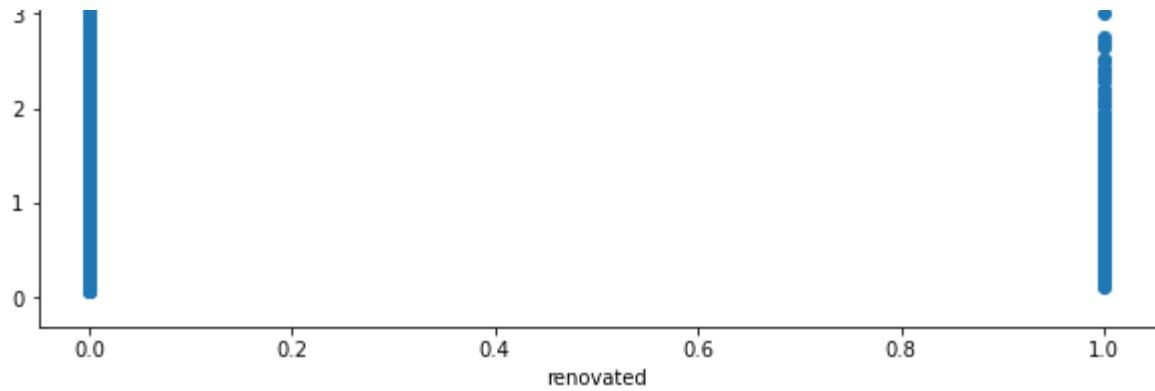

yr\_renovated vs. price

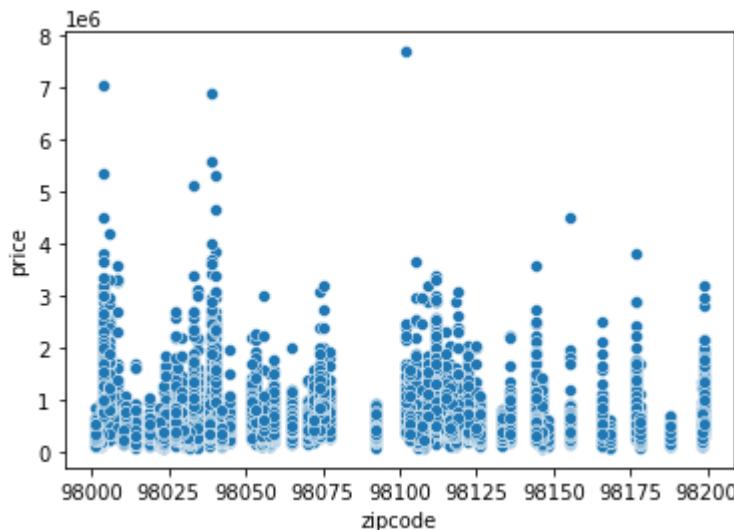

```
In [29]: sns.scatterplot(x=df['zipcode'], y=df['price']);
```

Zipcode is clearly a categorical column with no linear relationship with our target: 'price'. In order to keep this information in our model, we need to one hot encode this column.

```
In [30]: encoder = OneHotEncoder(sparse=False, drop='first')
cat_cols=['zipcode']
data_ohe = encoder.fit_transform(df[cat_cols])
df_ohe = pd.DataFrame(data_ohe, columns=encoder.get_feature_names(cat_cols), index=df.index)
```

21597 rows × 91 columns

We are ready to fit the data with a linear regression model now. Since the building and improving on the model will be an iterative process, we can write a function that will not only create the model but also show us our QQ Plot as well as the residual information so we can check for normality and homoscedasticity.

## Initial Model Prior to Addressing Multicollinearity

In [32]:

```
def model_lin_reg(df, target='price'):

    features = ' + '.join(df.drop(target, axis=1).columns)
    f = f'{target}~{features}'
    model = smf.ols(f, df).fit()
    display(model.summary())
    fig, ax = plt.subplots(ncols=2, figsize=(15,5))
    sm.graphics.qqplot(model.resid, line='45', fit=True, ax=ax[0])
    sns.scatterplot(x=model.predict(df, transform=True), y=model.resid, ax=ax[1])
    ax[1].set_ylabel('Residuals')
    ax[1].set_xlabel('Predicted')
    plt.axhline();
    return model
```

In [33]:

```
model_lin_reg(df=df_ohe)
```

**Omnibus:** 20806.796    **Durbin-Watson:** 1.995

**Prob(Omnibus):** 0.000    **Jarque-Bera (JB):** 4281101.044

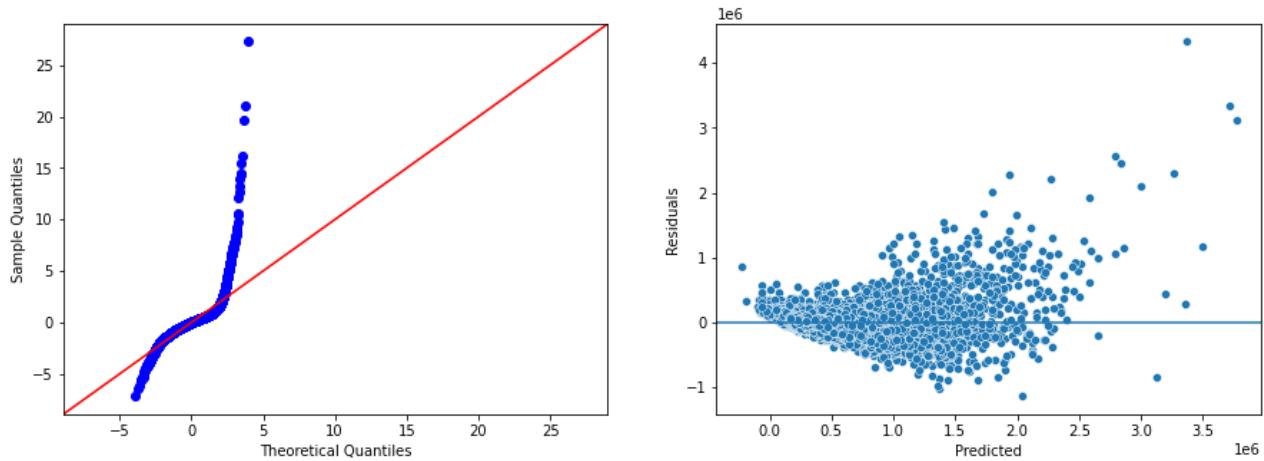

**Skew:** 4.158    **Prob(JB):** 0.00

**Kurtosis:** 71.471    **Cond. No.** 3.07e+13

### Notes:

- [1] Standard Errors assume that the covariance matrix of the errors is correctly specified.
- [2] The condition number is large, 3.07e+13. This might indicate that there are strong multicollinearity or other numerical problems.

Out[33]: <statsmodels.regression.linear\_model.RegressionResultsWrapper at 0x1bd1033a340>

Our baseline model's residuals does not meet the normality or the homoscedasticity assumption yet. We need to consider multicollinearity and address the columns that may be compromising the model. Additionally, we need to address outliers.

## Multicollinearity Check

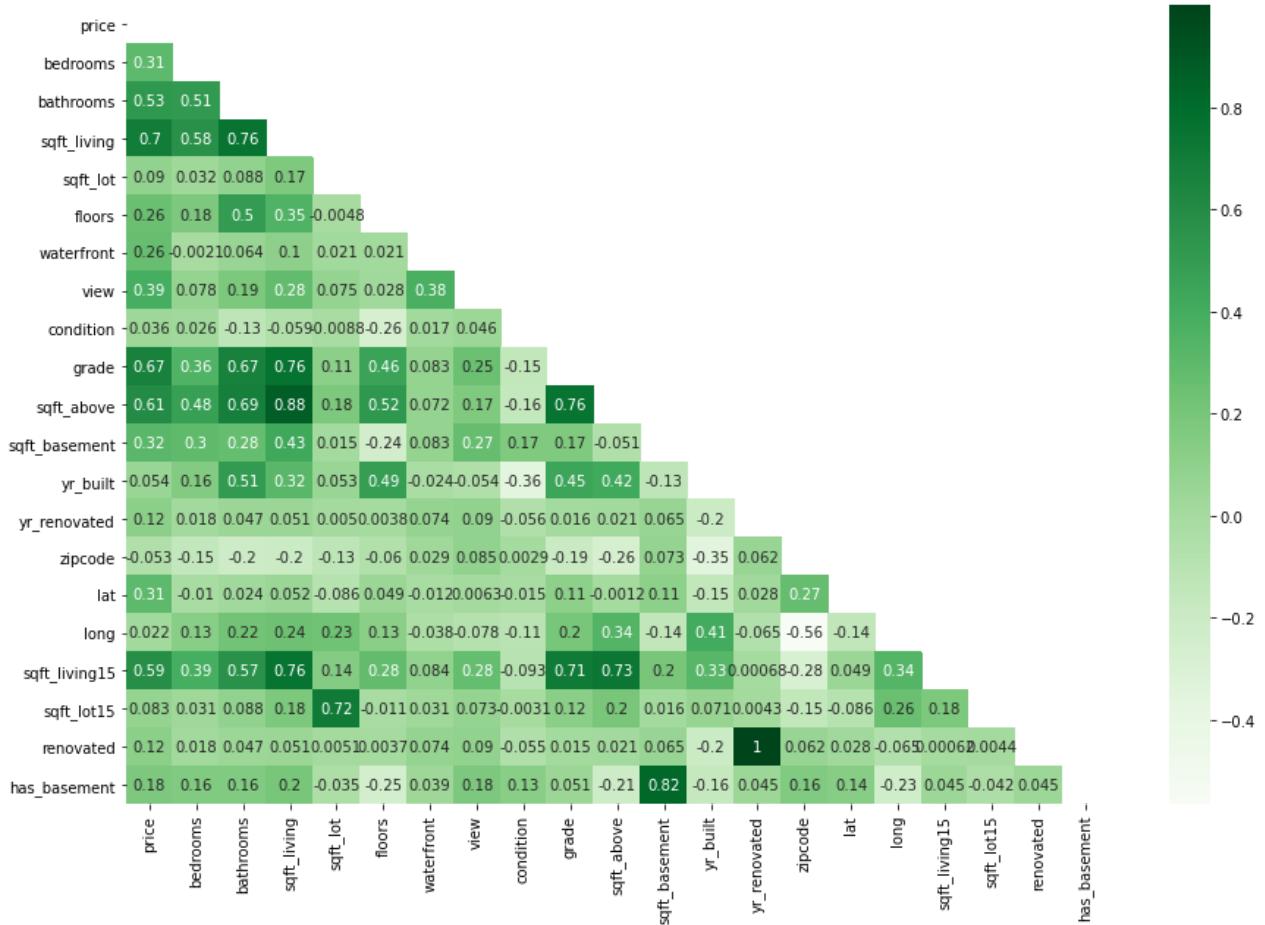

## Correlation Matrices - Before

It looks like there is multicollinearity between the different columns. To address these I will be creating matrices and removing columns that may be causing the issues.

```
In [34]: df.drop(['id', 'date'], axis=1, inplace=True)
```

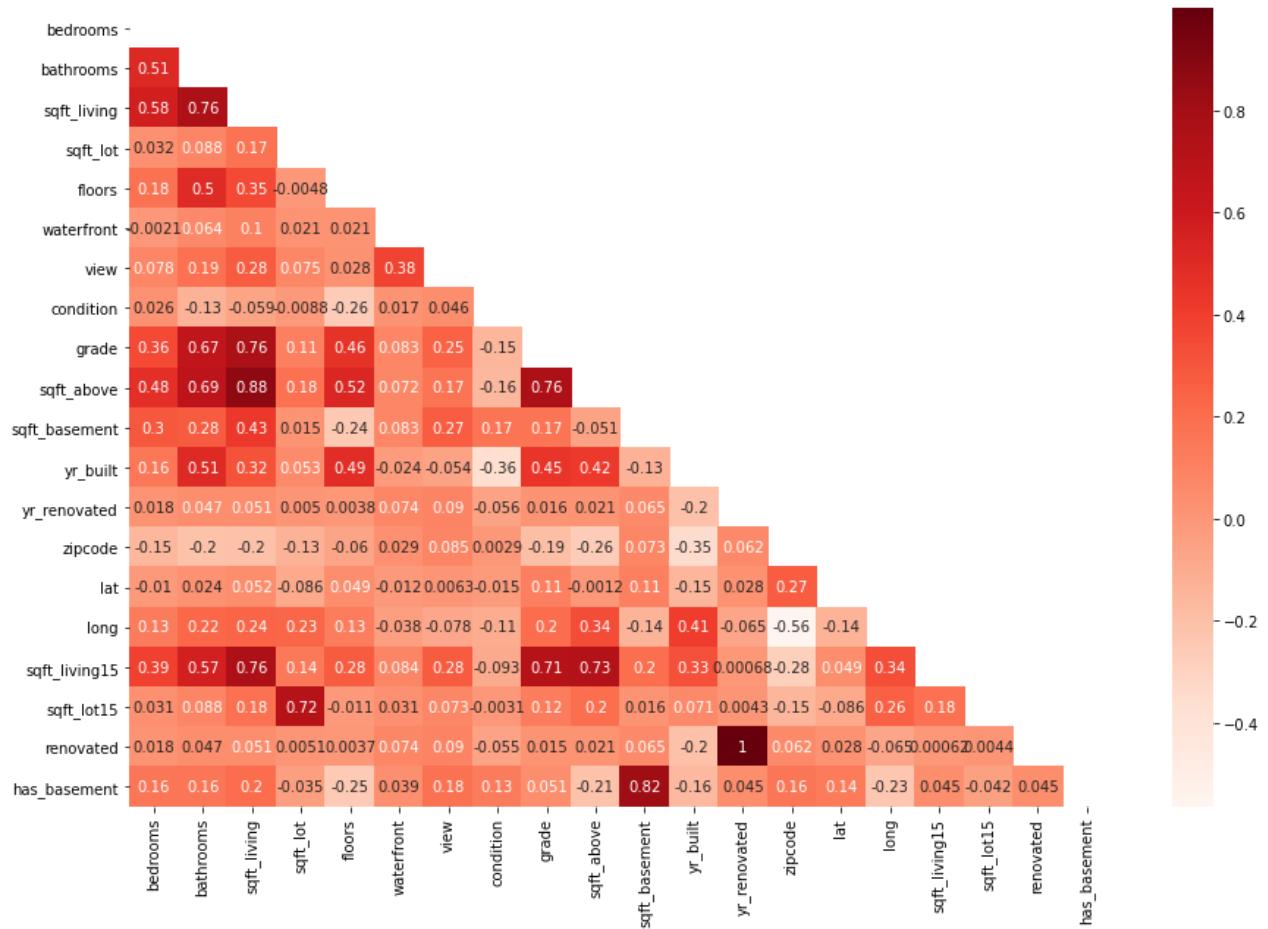

```
In [35]: mask = np.zeros_like(df.corr())
mask[np.triu_indices_from(mask)] = True
fig, ax = plt.subplots(figsize=(15,10))
sns.heatmap(df.corr(), annot=True, mask=mask, cmap='Greens')
```

```
Out[35]: <AxesSubplot:>
```

```
In [36]: mask = np.zeros_like(df.drop('price', axis=1).corr())
mask[np.triu_indices_from(mask)] = True
fig, ax = plt.subplots(figsize=(15,10))
sns.heatmap(df.drop('price', axis=1).corr(), annot=True, mask=mask, cmap='Reds')
```

```
Out[36]: <AxesSubplot:>
```

```
In [37]: df.corr()['price'].abs().sort_values(ascending=False)
```

```
Out[37]: price      1.000000
sqft_living    0.701917
grade         0.667951
sqft_above     0.605368
sqft_living15  0.585241
bathrooms      0.525906
view          0.393497
sqft_basement   0.321108
bedrooms       0.308787
lat            0.306692
waterfront      0.264306
floors          0.256804
has_basement     0.178264
yr_renovated    0.117855
renovated        0.117543
sqft_lot        0.089876
sqft_lot15      0.082845
yr_built        0.053953
zipcode         0.053402
condition       0.036056
long           0.022036
Name: price, dtype: float64
```

Looking at the correlation matrix of the original df (prior to being one hot encoded for simplicity of the visual), there seems to be strong correlations between a multitude of parameters when we take our cut-off point as 0.75. Dropping the 'sqft\_living' column will allow us to clear almost all the strong correlations. We are additionally not losing meaningful data since this column is equal to the sum of 'sqft\_above' and 'sqft\_basement'.

```
In [38]: df.drop('sqft_living', axis=1, inplace=True)
```

Since we have engineered a feature called 'has\_basement' using 'sqft\_basement' there is a high correlation between these columns as well. Since we are still keeping the basement information to a certain degree, we can also drop 'sqft\_basement'

```
In [39]: df.drop('sqft_basement', axis=1, inplace=True)
```

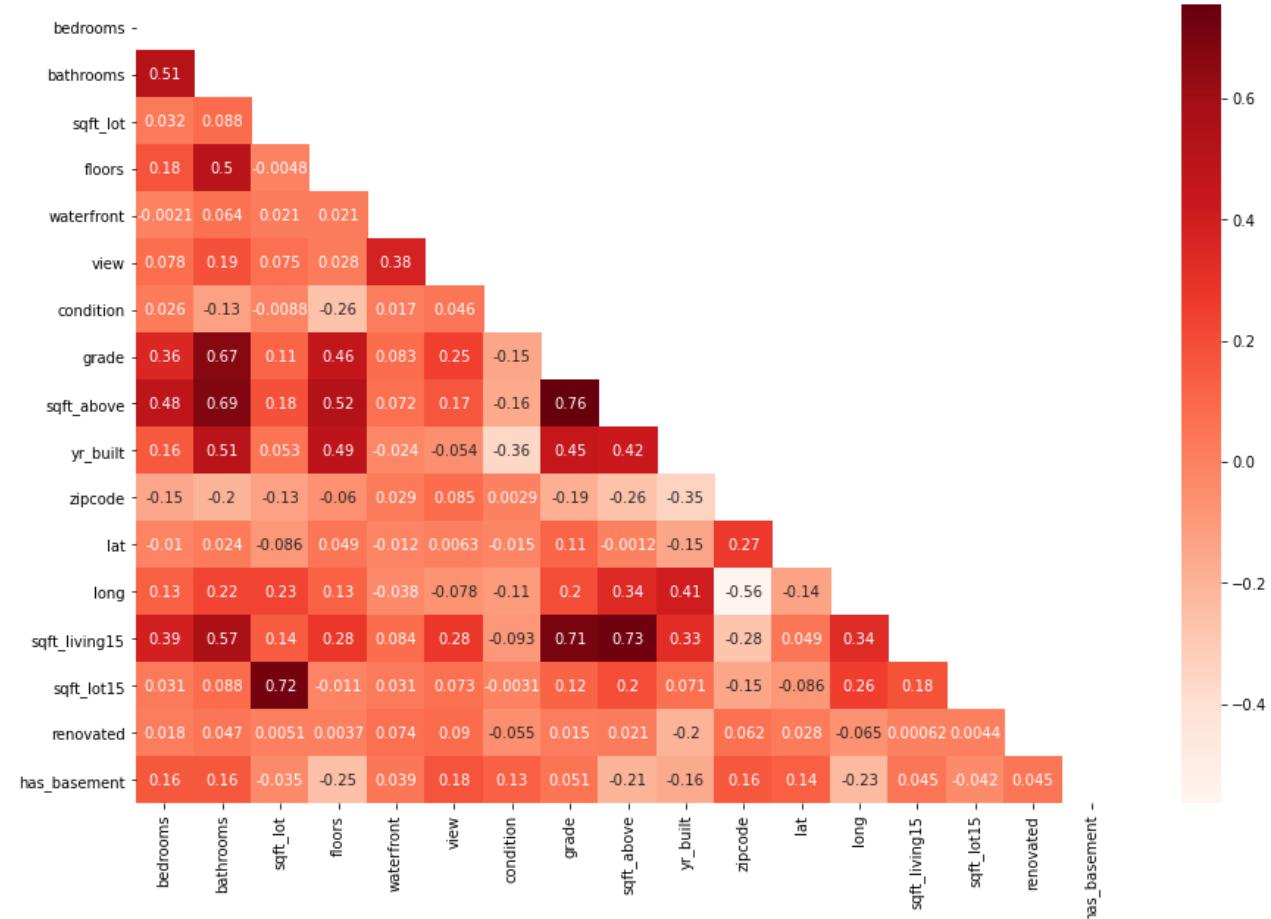

Similar to above, since we have engineered the column 'renovated' using 'yr\_renovated', we can also drop the 'yr\_renovated' column.

```
In [40]: df.drop('yr_renovated', axis=1, inplace=True)
```

## Correlation Matrix - After

```
In [41]: mask = np.zeros_like(df.drop('price', axis=1).corr())
mask[np.triu_indices_from(mask)] = True
fig, ax = plt.subplots(figsize=(15,10))
sns.heatmap(df.drop('price', axis=1).corr(), annot=True, mask=mask, cmap='Reds')
```

Out[41]: <AxesSubplot:>

Our correlation matrix looks much better with the exception of 'sqft\_above' and 'grade'. As this value is so close to our cut-off value of 0.75, we will be keeping it in to see if it causes any additional issues after adjustments to the model.

# MODEL

For this project we were asked to specifically use multiple linear regression (MLR) so our model will be an MLR model.

```
In [42]: drop_cols = ['id', 'date', 'sqft_living', 'sqft_basement', 'yr_renovated']
df_ohe.drop(drop_cols, axis=1, inplace=True)
```

```
In [43]: model_lin_reg(df=df_ohe)
```

<b>Prob(Omnibus):</b>	0.000	<b>Jarque-Bera (JB):</b>	5315892.814
<b>Skew:</b>	4.513	<b>Prob(JB):</b>	0.00
<b>Kurtosis:</b>	79.328	<b>Cond. No.</b>	2.84e+08

Notes:

- [1] Standard Errors assume that the covariance matrix of the errors is correctly specified.
- [2] The condition number is large, 2.84e+08. This might indicate that there are strong multicollinearity or other numerical problems.

Out[43]: <statsmodels.regression.linear\_model.RegressionResultsWrapper at 0x1bd77ac8a60>

The sqft\_lot15 p-value is higher than our alpha of 0.05 meaning that this coefficient is not statistically significant, so we can go ahead and drop this parameter.

In [44]: `df_ohe.drop('sqft_lot15', axis=1, inplace=True)`

We also wanted to create a feature to see if having a larger sqft (excluding the basement) would have any effect on the sale price of the home.

In [45]: `df_ohe['has_larger_sqft_than_neighbors'] = df_ohe['sqft_living15'] < df_ohe['sqft_above_basement']  
df_ohe['has_larger_sqft_than_neighbors'] = df_ohe['has_larger_sqft_than_neighbors'].astype(bool)  
df_ohe.drop('sqft_living15', axis=1, inplace=True)  
df_ohe.head()`

**Omnibus:** 21495.431    **Durbin-Watson:** 1.990

**Prob(Omnibus):** 0.000    **Jarque-Bera (JB):** 4815678.728

**Skew:** 4.381    **Prob(JB):** 0.00

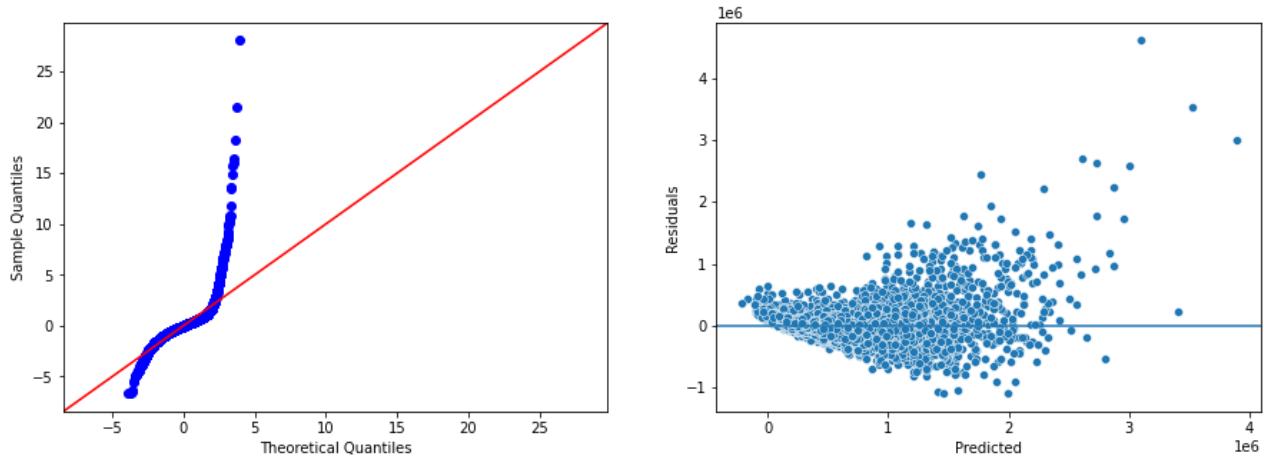

**Kurtosis:** 75.627    **Cond. No.** 2.47e+08

Notes:

[1] Standard Errors assume that the covariance matrix of the errors is correctly specified.

[2] The condition number is large, 2.47e+08. This might indicate that there are strong multicollinearity or other numerical problems.

Out[46]: <statsmodels.regression.linear\_model.RegressionResultsWrapper at 0x1bd1207c100>

As we can see our residuals still seem to not be fitting the normality and homoscedasticity assumptions. To address this we can move on to the outlier removal process.

## Outlier Removal

In [47]:

```
#Outlier Removal with the IQR method
#function snippet from Flatiron School Phase #2 Py Files.
```

```
def find_outliers_IQR(data):
    """Use Tukey's Method of outlier removal AKA InterQuartile-Range Rule
    and return boolean series where True indicates it is an outlier.
    - Calculates the range between the 75% and 25% quartiles
    - Outliers fall outside upper and lower limits, using a threshold of 1.5*IQR the 75

    IQR Range Calculation:
    res = df.describe()
    IQR = res['75%'] - res['25%']
    lower_limit = res['25%'] - 1.5*IQR
    upper_limit = res['75%'] + 1.5*IQR

    Args:
        data (Series,or ndarray): data to test for outliers.

    Returns:
        [boolean Series]: A True/False for each row use to slice outliers.

    EXAMPLE USE:
    >> idx_outs = find_outliers_df(df['AdjustedCompensation'])
    >> good_data = df[~idx_outs].copy()

    """
    df_b=data
    res= df_b.describe()

    IQR = res['75%'] - res['25%']
    lower_limit = res['25%'] - 1.5*IQR
    upper_limit = res['75%'] + 1.5*IQR
```

```
idx_outs = (df_b>upper_limit) | (df_b<lower_limit)

return idx_outs
```

In [48]: #Making a copy of df\_ohe for the second outlier removal process. Refer to next section.  
df\_IQR\_price = df\_ohe.copy()  
df\_IQR\_price

```

From our p-values, we can see that the latitude and longitude values are insignificant which means that we can go ahead and drop these coefficients.

```
In [54]: df_ohe.drop(['lat','long'], axis=1, inplace=True)

**Omnibus:** 1494.930    **Durbin-Watson:** 1.993

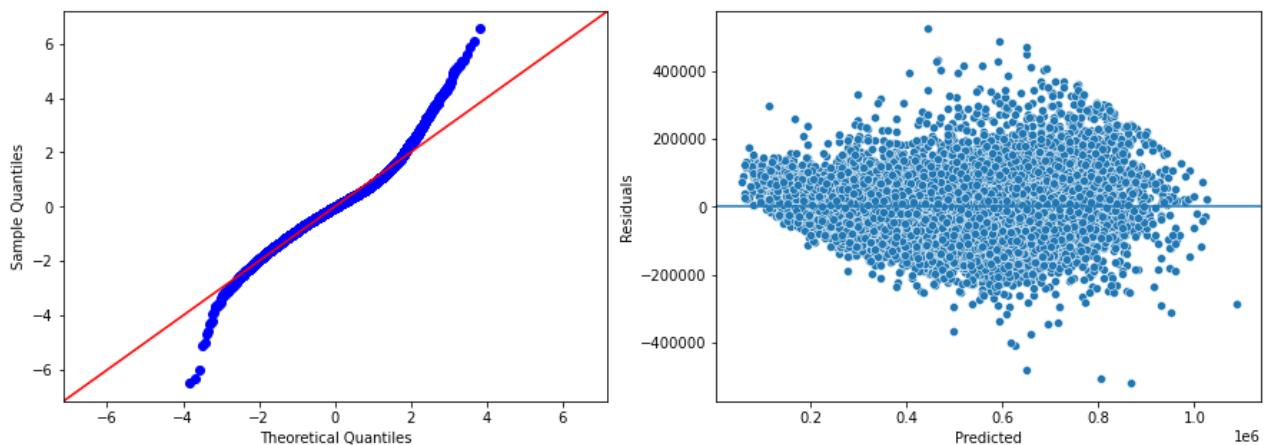

**Prob(Omnibus):** 0.000    **Jarque-Bera (JB):** 5136.551

**Skew:** 0.438    **Prob(JB):** 0.00

**Kurtosis:** 5.585    **Cond. No.** 9.83e+05

Notes:

- [1] Standard Errors assume that the covariance matrix of the errors is correctly specified.
- [2] The condition number is large, 9.83e+05. This might indicate that there are strong multicollinearity or other numerical problems.

Thanks to the IQR outlier removal process, our residuals seem to now be better fitting into the normality and homoscedasticity assumptions.

21596	325000.0	2	0.75	1076	2.0	0.0	0.0	3	7	102

16556 rows × 83 columns

Since we removed outliers from all numeric columns including our target 'price', we are left with 16556 rows compared to the 21597 we started off with. It makes more sense to remove outliers based on the prices of the homes rather than removing outliers in every single column. This has a potential upside of allowing for there to be more data points and therefore a more accurate model overall.

## Removing Outliers Based on Price Only

In [57]: df\_IQR\_price = df\_IQR\_price[find\_outliers\_IQR(df\_IQR\_price['price'])==False]  
df\_IQR\_price

Out[57]:

	price	bedrooms	bathrooms	sqft_lot	floors	waterfront	view	condition	grade	sqft_abov
--	-------	----------	-----------	----------	--------	------------	------	-----------	-------	-----------

21595	400000.0	3	2.50	2388	2.0	0.0	0.0	3	8	160
21596	325000.0	2	0.75	1076	2.0	0.0	0.0	3	7	102

20439 rows × 85 columns

As seen above, we are left with approximately 4,000 more data points when we only remove outliers based on price. We still should take a look at the model and whether the residuals have adjusted similarly to the prior model.

In [58]: `model = model_lin_reg(df=df_IQR_price)`

**Omnibus:** 1997.283    **Durbin-Watson:** 1.988

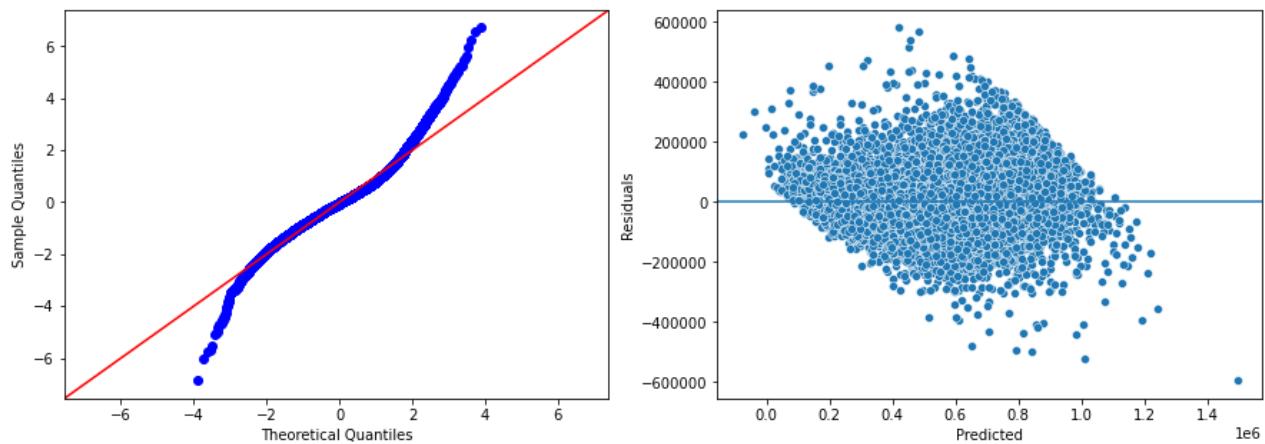

**Prob(Omnibus):** 0.000    **Jarque-Bera (JB):** 7373.063

**Skew:** 0.457    **Prob(JB):** 0.00

**Kurtosis:** 5.797    **Cond. No.** 2.38e+08

Notes:

- [1] Standard Errors assume that the covariance matrix of the errors is correctly specified.
- [2] The condition number is large, 2.38e+08. This might indicate that there are strong multicollinearity or other numerical problems.

Our model has a higher R-squared value at 0.826 compared to the prior model at 0.820 and has more data points. We will keep iterating on this model instead of using the prior one due to this reason.

```
In [59]: model.pvalues[model.pvalues>0.05]
```

```
Out[59]: bedrooms      0.773793
 zipcode_98002    0.436613
 zipcode_98003    0.106306
 zipcode_98030    0.853040
 zipcode_98031    0.775410
```

```
zipcode_98032    0.053031
zipcode_98042    0.158899

zipcode_98188    0.298986
zipcode_98198    0.490884
dtype: float64
```

Interestingly, we are seeing that bedrooms are no longer a significant coefficient, and therefore not a significant parameter to define the sales price of a home based on our model. We can keep the 'bedrooms' parameter in for the time being to see if anything changes when we scale the model to compare our parameters' effects against each other. A quick note compared to the previous model we had is that 'lat' and 'long' are significant in this model so we are keeping them in.

<b>Kurtosis:</b>	5.797	<b>Cond. No.</b>	291.			

Notes:

[1] Standard Errors assume that the covariance matrix of the errors is correctly specified.

Even after scaling, the bedrooms coefficient seems to be insignificant. This could be due to the actual sqft mattering more and being a better predictor of sales price. We can go ahead and drop the bedrooms column and take a look at the coefficients for further insight.

```
In [66]: df_scaled.drop('bedrooms', axis=1, inplace=True)
model = model_lin_reg(df=df_scaled)
```

#     sns.pointplot(x= 'Category', y='price', data=mean_price_per_cat, order=order)

```

As can be seen above, as the square footage of the house increased sale price of the home also tended to increase with it. Even though there is a spread of price at each category of square footage and therefore some overlaps between them, there is a clear positive trend between sale price and square footage above ground. Additionally, it should be noted that as the square footage increases the minimum sale price of the category is consistently increasing as well indicating that even if the house may not be optimal per other parameters, having a certain amount of square footage tends to make it more valuable.

```

ax.set_ylabel('Sale Price ($)')
ax.set_title("Relationship of Sale Price with Above Ground Sqft and Having a Basement")
ax.yaxis.set_major_formatter(FuncFormatter(lambda x, p: format(int(x), ',')))
ax.xaxis.set_ticks(range(0,6500,500))
ax.set_ylim(0, 1300000)
plt.gcf().set_size_inches(12,7);

```

When we look at the relationship between square footage above ground and the home's sale price again, but add in a second parameter to define whether the house had a basement or not, the houses with a basement have a slightly more positive relationship with the sale price. So if a house had a basement, it tended to have a slightly higher price than a comparable home. This is visible from the difference of slopes between the two lines shown above where the green line is diverging from the blue line in a positive way.

    ax.yaxis.set_major_formatter(FuncFormatter(lambda x, p: format(int(x), ',')))
    ax.set_yticks(range(0,1300000,100000))
```

Another interesting, but also expected relationship is between the grade of finishes and the sale price. Houses that had higher grades of finishes and a better construction quality sold for higher prices.

```
In [89]: from matplotlib.ticker import FuncFormatter
with plt.style.context('seaborn-whitegrid'):

    sns.lmplot(x='sqft_above', y='price', data=df_grade_sqft, hue='Category',
                aspect=2, scatter_kws=dict(alpha=0.7), palette=sns.color_palette("hls",
                ax = plt.gca()
                ax.set_xlabel('Sqft Above Ground (Excluding Basement)')
                ax.set_ylabel('Sale Price ($)')
                ax.set_title("Relationship of Sale Price with Above Ground Sqft and Grade")
                ax.yaxis.set_major_formatter(FuncFormatter(lambda x, p: format(int(x), ',')))
```

```
ax.xaxis.set_ticks(range(0,6500,500))
ax.set_xlim(0, 1300000)
plt.gcf().set_size_inches(12,7);
```

When grade is plotted with square footage above ground, the relationship shown in the previous visual becomes even more apparent. As can be seen from the different colored data points, above average homes tended to have a higher sale price. The regression lines for average and above average have a higher positive slope compared to the below average homes, which means that as the square footage of a home increases, the higher graded homes will tend to have higher prices.

## CONCLUSIONS & RECOMMENDATIONS

Even though renovations are usually a lot of effort and stressful to lots of homeowners, they may help increase the property's value. To sum up, our analysis for King County, Washington showed the following:

- Increasing the square footage above ground tends to increase the house's value.
- Focusing on the grade of finishes and the quality of construction as a whole tends to pay dividends when it comes to selling the house.
- Having a basement is the third most effective parameter in increasing a home's sale price.

Our first recommendation based on our findings above would be for the homeowner to renovate their house and add livable above ground square footage to the property. This could be in the shape of an added extension to the home or a simpler approach of finishing the attic space.

Secondly, we would advise the homeowner to also focus their renovation efforts on the finishes and quality of the materials that they would be choosing to use. This could include components such as kitchen countertop material, cabinetry design, bathroom fixtures, general lighting design and fixture choices inside and outside the house, flooring.

Lastly, we would propose that the homeowner add a basement to their home. It should be noted that since we do not know what the construction costs of this undertaking would be like versus the gain in the home's sale price, it is difficult to predict the outcome (refer to the Limitations & Next Steps section for more information on this). However, based on our model, we found that having a basement for homes was the third most effective parameter. If the home already has a basement, but the basement is unfinished, our recommendation would be for the homeowner to make the basement an occupiable space by finishing it.

## Limitations & Next Steps

Given more time and information about what the homeowner's renovation budget would be, we would have wanted to analyze whether these top 3 parameters would truly be the most effective in bringing a net value increase since a renovation such as adding a basement to a home would be very costly and may not end up returning a net value increase. Additionally, the construction costs in the state of Washington may be higher than other states due to factors such as permitting, material costs, logistical challenges etc. which may effect the net value increase as well. Furthermore, having information about whether the homeowner is thinking about living in the renovated house or renting it out would allow us to fine tune our analysis and bring more valuable insight.
